## **Zusammenfassung**

Die Gene der T-cell leukemia/lymphoma 1 (TCL1) Familie wurden erstmals aufgrund ihrer Beteiligung an spezifischen Chromosomenaberrationen in reifen T-Zell-Erkrankungen identifiziert. Bei Menschen besteht diese Familie aus den drei Genen TCL1A, MTCP1 und TCL1B (auch TML1 genannt). Normalerweise werden diese Gene in Lymphozyten während der frühen B- und T-Zell Entwicklung und während der frühen Embryogenese exprimiert. Überexpression von TCL1A wird in vielen reifen B-Zell- und T-Zell-Tumoren detektiert, einschließlich der chronisch lymphatischen Leukämie (CLL) und der T-Zell Prolymphozyten-Leukämie (T-PLL). Expression von TCL1A oder MTCP1 in T Zellen transgener Mäuse führt zur Entwicklung T-PLL-ähnlicher Erkrankungen nach einer langen Latenzzeit (>15 Monate). In diesen Untersuchungen wurden zwei unterschiedliche Promotoren für die T-Zell-spezifische Expression verwendet, die keinen direkten Vergleich dieser zwei Onkogene zulassen. Studien zum Transformationspotenzial von TML1 wurden bislang nicht veröffentlicht. Im ersten Teil dieser Arbeit wurde deshalb das onkogene Potenzial der TCL1 Gene verglichen, indem gamma-retrovirale Vektoren für humanes TCL1A, MTCP1 und TML1 in hämatopoetische Stammzellen/hämatopoetische Vorläuferzellen (HSC/HPC) von Wildtyp-Mäusen eingebracht und in Wildtyp-Empfänger transplantiert wurden. TCL1A und MTCP1 Empfängermäuse entwickelten überwiegend B-Zell-Tumore nach einer medianen Überlebenszeit von 388 Tagen, beziehungsweise 394 Tagen. Somit beweisen diese Daten, dass TCL1A und MTCP1 Onkogene mit vergleichbarem onkogenem Potenzial sind und zeigen zum ersten Mal, dass MTCP1 nicht nur ein T-Zell-Onkogen ist, sondern auch in der Lage ist, B Zellen zu transformieren. Das dritte Familienmitglied TML1 induzierte die Entwicklung von unreifen T-Zell-Malignitäten in wenigen Mäusen. Obwohl TML1 ein schwächeres Onkogen zu sein scheint, liefert diese Studie erste Hinweise für dessen onkogene Funktion. Jedoch besteht in diesem Modell das Risiko der Insertionsmutagenese, die möglicherweise zur Induktion oder Beschleunigung der Tumorentwicklung beigetragen hat.

Untersuchungen zur molekularen Funktion haben gezeigt, dass die Stimulierung des Antigenrezeptors (TCR) die Interaktion zwischen TCL1A und der Ser/Thr-Kinase AKT an der Zellmembran induziert, gefolgt von einer Kerntranslokation. Darauf folgende Studien zeigten, dass TCL1A auch mit anderen Signalmolekülen im Cytosol (p300, ATM) und im Kern (Jun, Fos) interagiert. Zusammen implizieren diese Daten, dass TCL1A Kompartiment-spezifische Funktionen hat. Aus diesem Grund wurde das

Transformationspotenzial von zwei Kompartiment-spezifischen TCL1A Varianten in dem zuvor beschriebenen Transplantationsmodell untersucht, indem eine myristoylierte (Membran-lokalisierende) Variante (myr-TCL1A) und eine Kern-lokalisierende Variante (nls-TCL1A) retroviral in HSC/HPC von Mäusen eingebracht wurden. Empfänger-mäuse von myr-TCL1A und nls-TCL1A transduzierten HSC/HPC entwickelten überwiegend B-Zell-Tumore nach einer medianen Überlebenszeit von 360 Tagen beziehungsweise 349 Tagen. Demnach zeigte sich eine signifikant kürzere Latenzzeit für nls-TCL1A im Vergleich zum zuvor beschriebenen generischen TCL1A. Die Genexpressionsanalyse dieser Tumore offenbarte größere Ähnlichkeiten zwischen den Expressionsprofilen von Tumoren, die durch TCL1A und nls-TCL1A induziert wurden. Zusammen implizieren diese Daten, dass die überwiegend onkogene Funktion von TCL1A auf dessen Vorkommen im Kern beruhen könnte.

Aufbauend auf publizierten *in vitro* Studien, die beschreiben, dass TCL1 die TCR-Signalisierung verstärkt (z.B. via AKT), wurde im zweiten Teil dieser Arbeit untersucht, ob und wie sich TCR Stimulation auf das Transformationspotenzial von TCL1A auswirkt. Hierfür wurden reife OT-1 T Zellen, dessen monoklonaler TCR spezifisch Ovalbumin (OVA) erkennt, retroviral mit TCL1A und seinen myr/nls Varianten transduziert und wiederholt *in vivo* mit OVA-Peptide stimuliert. TCR stimulierte Empfänger-mäuse von TCL1A transduzierten T Zellen zeigten eine signifikante Beschleunigung der Leukämie-Entwicklung und eine verringerte mediane Überlebenszeit von 305 Tagen im Vergleich zu unstimulierten TCL1A Empfängern (417 Tage). Stimulierte und unstimulierte Empfänger-mäuse zeigten vergleichbare Unterschiede in der Überlebenszeit für die Kompartiment-spezifischen TCL1A Varianten und seine generische Form. Diese Daten implizieren eine pro-leukämogene Zusammenarbeit von TCL1A und TCR Signalen, die möglicherweise in zukünftigen Therapiekonzepten berücksichtigt werden kann.

## **Abstract**

The members of the T-cell leukemia/lymphoma 1 (TCL1) gene family were first identified through their involvement in specific chromosomal aberrations in mature T-cell malignancies. In humans this family consists of 3 genes: TCL1A, MTCP1, and TCL1B (also called TML1). Normally, these genes are expressed in lymphocytes during early B- and T-cell development and during initial embryogenesis. Overexpressed TCL1A is found in many mature B-cell and T-cell tumors, including chronic lymphocytic leukemia (CLL) and T-cell prolymphocytic leukemia (T-PLL). Transgenic mice expressing TCL1A or MTCP1 in T cells develop T-PLL-like diseases after a long latency period (>15months). These transgenes employ two different promoters to drive T-cell specific expression, which does not allow a direct comparison of the two oncogenes. Studies on the transforming potential of TML1 have not been published yet. Therefore, in the first part of this thesis, the oncogenic potential of TCL1 genes was comparatively evaluated by using gamma-retroviral vectors to introduce human TCL1A, MTCP1, and TML1 into hematopoietic stem cells/hematopoietic progenitor cells (HSC/HPC) of wild type mice that were transplanted into wild type recipients. TCL1A and MTCP1 recipient mice predominantly developed B-cell malignancies after a median survival of 388 days and 394 days, respectively. The presented data indicates that TCL1A and MTCP1 are oncogenes with comparable oncogenic potential and shows for the first time that MTCP1 is not only a T-cell oncogene, but is able to transform B cells as well. The third family member TML1 induced the development of immature T-cell malignancies in only a few mice. Although TML1 appeared to be a weaker oncogene, this study provides first evidence for its oncogenic function. However, there is a risk for insertional mutagenesis in this model that might have contributed to induction or acceleration of tumor development.

At the level of molecular function, it had been shown that engagement of the antigen receptor (TCR) induces the interaction of TCL1A with the ser/thr kinase AKT, initially at the cell membrane followed by nuclear translocation. Subsequent studies described TCL1A to engage with other signaling molecules in the cytosol (p300, ATM) and in the nucleus (Jun, Fos). Together, these data suggest that TCL1A has compartment-specific functions. Consequently, the transforming potential of compartment-targeted TCL1A variants was evaluated in the above described transplantation model by retroviral expression of a membrane localizing myristoylated (myr-TCL1A) and a nuclear localizing (nls-TCL1A) variant in murine HSC/HPC. Recipients of HSC/HPC transduced with myr-TCL1A and nls-TCL1A predominantly developed B-cell malignancies after a median survival of 360 days

and 349 days, respectively. There was a significantly shorter latency period for nls-TCL1A compared to the previously described generic TCL1A. Gene expression analysis of these tumors revealed higher similarities between expression profiles of tumors induced by TCL1A and nls-TCL1A. Together these data implicate that TCL1A's predominant oncogenic function might rely on its nuclear presence.

Expanding on previously reported in vitro observations of TCL1A to enhance TCR signaling (e.g. via AKT), the second part of this thesis aims to understand if and how TCR stimulation affects the transforming potential of TCL1A. Mature OT-1 T cells carrying monoclonal TCR's that specifically recognize ovalbumin (OVA) were retrovirally transduced with TCL1A and its myr/nls variants and repeatedly stimulated in vivo with OVA-peptides. TCR stimulated recipient mice of TCL1A transduced T cells showed a significantly accelerated leukemic outgrowth and a reduced median survival of 305 days, when compared to unstimulated recipients (417 days). Stimulated vs unstimulated recipient mice showed comparable differences in survival across the compartment-targeted TCL1A variants and its generic form. These data strongly implicate a pro-leukemogenic cooperation of TCL1A and TCR signals that might be actionable in upcoming interventional designs.

# 1. Introduction

## 1.1 T lymphocytes

As part of the adaptive immune system, T lymphocytes are responsible for cell-mediated immune responses. They are able to recognize all kinds of foreign antigens through the expression of a highly variable antigen-receptor: the T-cell receptor (TCR). T cells cannot directly recognize pathogens. Their activation and function relies on other cells that display smaller fragments of processed proteins via a major histocompatibility complex (MHC) molecule. The majority of T cells have a TCR that consists of an  $\alpha$ - and  $\beta$ -chain, whereas a minor population expresses  $\gamma/\delta$ -TCRs. This thesis is focused on the more common  $\alpha/\beta$ -T cells, which are generally referred to as T cells hereafter.

### 1.1.1 T-cell development

T lymphocytes originate from hematopoietic stem cells (HSC) in the bone marrow (BM). These stem cells differentiate into myeloid and lymphoid progenitors that give rise to the cellular components of the innate and adaptive immune system. For T-cell development (Figure 1-1), common lymphoid progenitors (CLPs) migrate to the thymus and pass through distinct developmental stages. As these progenitors still lack CD4 and CD8 co-receptor expression, they are referred to as double-negative (DN) thymocytes. Based on the expression of the adhesion molecule CD44 and the IL-2 receptor alpha-subunit CD25, DN thymocytes are subdivided into four stages: DN1 (CD44<sup>+</sup>, CD25<sup>-</sup>), DN2 (CD44<sup>+</sup>, CD25<sup>+</sup>), DN3 (CD44<sup>-</sup>, CD25<sup>+</sup>) and DN4 (CD44<sup>-</sup>, CD25<sup>-</sup>) (1). Expression of recombination-activating genes (RAG1 and RAG2) during the DN2 stage initiates rearrangement of the TCR  $\beta$ -chain (2,3). The TCR  $\beta$ -chain is then paired with a pre-T $\alpha$ -chain to form a pre-TCR at the DN3 stage (4). Only thymocytes that signal through the pre-TCR will be able to transition to the DN4 stage (5). Rearrangement of the TCR  $\alpha$ -chain in DN4 thymocytes results in expression of a mature  $\alpha\beta$ -TCR assembled with CD3/ $\zeta$  proteins. These cells start to express CD4 and CD8, thereby forming a population of double-positive (DP) thymocytes. At this stage, different selection processes take place that only allow maturation of thymocytes that recognize presented MHC-bound self-peptides (spMHC) at the right strength: death by neglect, negative selection and positive selection.

**Figure 1-1: T-cell development in the thymus**

HSCs give rise to CLPs that migrate to the thymus. There, they go through four different developmental stages as double-negative ( $CD4/CD8^-$ ) thymocytes (DN1-4). Successful pre-TCR expression leads to transition into double positive (DP) ( $CD4^+/CD8^+$ ) thymocytes and expression of a fully rearranged TCR. The fate of the DP thymocytes depends on their TCRs' affinity to MHC-bound self-peptides presented by cortical epithelial cells. Cells that bind too weakly will not receive a survival signal and die by neglect. DP thymocytes that interact with MHC class II molecules at the right strength develop into  $CD4^+$  cells, whereas an appropriate interaction with MHC class I molecules leads to maturation into  $CD8^+$  cells. These cells will receive apoptotic signals, if the interaction with these molecules is too strong. After successful maturation, naïve T cells migrate to the periphery. Adapted from Germain et al (6).

DP thymocytes that fail to interact with MHC-bound ligands will die by neglect, as they do not receive intracellular survival signals. A strong interaction between the TCR and the presented self-peptide on the other hand leads to induction of apoptosis (negative selection), thereby eliminating potentially self-reactive T cells. Only thymocytes that bind to self-peptide at low intensity receive signals that enable further maturation (positive selection). Depending on the recognition of MHC class I or MHC class II molecules, these cells develop into mature  $CD4$  or  $CD8$  single-positive (SP) T cells (7). Upon successful maturation and selection,

mature T cells leave the thymus and enter the peripheral blood to migrate to secondary lymphoid tissues.

### **1.1.2 T-cell subsets**

Various mature T-cell subsets can be distinguished based on their function and expression of cell-surface markers. Co-receptor expression on these cells allows a broad division into two T-cell lineages: CD4 T-helper (Th) cells and cytotoxic CD8 T cells (CTL). CD4 T cells are mainly responsible for activating other immune cells through cytokine release. They recognize peptides presented by MHC class II molecules that are exclusively found on specialized antigen presenting cells (APCs), such as dendritic cells, macrophages and B cells (8). CD8 T cells are capable of killing infected cells and interact with MHC class I peptide complexes that are found on all nucleated cells (8). The functional status divides these lineages further into naïve, effector and memory cells (9). After their development in the thymus, naïve T cells circulate lymphoid tissue to screen for presented antigen. Upon antigen encounter, these cells proliferate and differentiate into effector T cells. Following the resolution of an immune response, most effector T cells die and only a small number of memory T cells remains that can quickly be reactivated at a second encounter with the same antigen (10). These basic functional groups can be distinguished based on specific marker expression. Differential isoform expression of the protein tyrosine phosphatase CD45 allows a general discrimination between naïve ( $CD45RA^+$ ) and effector/memory ( $CD45RO^+$ ) T cells in humans, but not in mice (11,12). In both species, the adhesion molecule CD62L and the chemokine receptor *CCR7* are found on naïve and central memory T cells as these homing receptors enable migration within the lymphoid tissue (9). Effector T cells down-regulate these two markers and up-regulate E-selectin ligands, such as CD44, that enable migration to the site of infection (10). In addition, they up-regulate surface expression of CD69 and CD40 ligand (CD40L). The role of CD69 in activated T cells is still unclear. It was thought to act as a co-stimulatory molecule, but more recent studies argue with that perception and suggest roles in negative regulation and T-cell polarization (13). CD40L interacts with CD40 on APCs and induces up-regulation of the co-stimulatory proteins CD80 and CD86. Although the interaction between CD40L and CD40 plays a major role in the effector functions of CD4 T cells to activate APCs, it is also found on CD8 T cells (14). Moreover, activated  $CD8^+$  CTLs are characterized by the production of perforin and granzyme (10). These cytolytic

proteins are required for inducing cell death in their target cells. Effector CD4<sup>+</sup> Th cells account for a heterogeneous group that can be further subdivided into Th1, Th2, Th9, Th17, Th22, Tfh (follicular Th) and Treg (regulatory T cells) based on their cytokine profile (15). Once an infection is cleared, most activation markers are down-regulated with exception of CD44. Subsequently, two populations of memory T cells remain: central memory (T<sub>CM</sub>) and effector memory (T<sub>EM</sub>) T cells. T<sub>CM</sub> are CCR7<sup>+</sup> CD62L<sup>+</sup> and CD44<sup>+</sup>, reside in the lymph node (LN), produce IL-2 and proliferate extensively (13). T<sub>EM</sub> lack CCR7 and CD62L expression and are found primarily in non-lymphoid tissue (16,17). They are less proliferative than T<sub>CM</sub> and produce a variety of effector cytokines, such as IL-4, IL-5 and interferon- $\gamma$  (IFN- $\gamma$ ) (16).

### **1.1.3 T-cell receptor engagement and signaling**

The TCR consists of the two polypeptide chains TCR $\alpha$  and TCR $\beta$ . Each cell expresses a unique TCR that is generated during their development in the thymus by rearrangement of TCR gene segments. This process is called V(D)J recombination according to the involved variable (V), diversity (D) and joining (J) gene segments and has the potential to generate  $>10^{15}$  different TCRs in mice and  $>10^{18}$  TCRs in humans (18). Fully rearranged TCR chains are composed of a constant region and a variable region (Figure 1-2A). Complementarity determining regions (CDRs) within the variable region are primarily responsible for antigen binding. TCR diversity allows recognition of a broad range of different antigens presented by MHC molecules. Typically, MHC class I molecules present protein fragments of endogenous pathogens to CD8 T cells, whereas MHC class II molecules present peptides of exogenous pathogens taken up by APCs to CD4 T cells. However, some APCs are also able to present extracellular antigens via MHC class I molecules through a process called cross-presentation. MHC class I molecules have a closed binding groove and therefore bind short peptides with a length between 8-15 amino acids (19). In contrast, MHC class II molecules have an open binding groove that presents larger peptides with a length between 11-30 amino acids (19). The TCR is expressed on the cell surface in a complex with accessory molecules. In addition to the TCR $\alpha$ - and TCR $\beta$ -chain, this complex consists of one CD3 $\gamma$ , one CD3 $\delta$  and two CD3 $\epsilon$  chains, as well as one intracytoplasmic  $\zeta$  homodimer (Figure 1-2B) (20).

Activation of naïve T cells requires two signals provided by APCs: a foreign antigen bound to a MHC molecule (signal one) and a co-stimulatory protein (CD80 or CD86) (signal two) (18). Signal one is recognized by the TCR and signal two by the co-receptor CD28 on T cells. Absence of either one of these signals leads to apoptosis or a state of anergy (18). In addition, the co-receptor CD4 or CD8 stabilizes the interaction between the TCR and MHC complex by binding to the respective MHC class (Figure 1-2B).

**Figure 1-2: TCR structure and engagement**

(A) The TCR consists of a TCR $\alpha$ - and TCR $\beta$ -chain. Each chain is composed of a variable and a constant region. Adapted from Murphy (21). (B) The TCR is expressed as a complex with CD3 and accessory chains on the cell surface. In association with the co-receptor, this complex is responsible for recognition of MHC-bound peptides and initiation of T-cell activation. Adapted from Gascoigne et al (22).

Upon antigen recognition, the src-family kinases Lck and Fyn are activated and subsequently phosphorylate immunoreceptor tyrosine-based activation motifs (ITAMs) within the cytoplasmic domains of the CD3 and accessory  $\zeta$  chains. Phosphorylation of the ITAMs leads to recruitment and activation of the tyrosine kinase ZAP-70, which propagates the TCR

signal by phosphorylating two critical adaptor molecules: SH2 domain-containing leukocyte protein of 76 kDa (SLP-76) and the linker for activation of T cells (LAT) (Figure 1-3) (23). Together they form a membrane-associated signaling complex that recruits various adapter and effector molecules, including phospholipase- $\gamma$  (PLC $\gamma$ ). PLC $\gamma$  is phosphorylated within this complex. Subsequently, PLC $\gamma$  cleaves membrane-bound phosphatidylinositol biphosphate (PtdInsP<sub>2</sub>) into diacyl glycerol (DAG) and inositol trisphosphate (InsP<sub>3</sub>) (24).

**Figure 1-3: TCR signaling pathway**

Engagement of the TCR leads to activation of the kinases Lck and ZAP-70, followed by formation of a multimolecular signaling complex at the membrane involving the two adaptor proteins SLP70 and LAT. The resulting activation of PLC $\gamma$  induces cleaving of PtdInsP<sub>2</sub> into DAG and InsP<sub>3</sub>, which in turn activates various downstream signaling pathways, such as calcium signaling, MAPK signaling and NF $\kappa$ B signaling pathways. At the same time, co-stimulation through CD28 induces the PI3K/AKT signaling pathway. Ultimately, all pathways activate transcription factors that induce transcription of IL-2 and other pro-inflammatory genes. Adapted from Pollizzi et al (25).

InsP<sub>3</sub> binds to calcium channels on the endoplasmic reticulum (ER) membrane, thereby releasing stored calcium into the cytosol. Calcium induces conformational changes in the messenger protein calmodulin that lead to recruitment of serine/threonine protein phosphatase calcineurin. Activated calcineurin desphosphorylates the transcription factor nuclear factor of activated T cells (NFAT), allowing NFAT to enter the nucleus (26). In the nucleus, NFAT cooperates with other transcription factors to induce transcription of IL-2 and other pro-inflammatory genes. Parallel to calcium signaling, DAG recruits and activates the signaling molecules Ras and PKC $\theta$  (27). Ras triggers the MAPK/ERK pathway, whereas PKC $\theta$  activates the NF- $\kappa$ B pathway. The kinase cascade in the MAPK/ERK pathway follows successive activation of the mitogen-activated protein kinases (MAPK) Raf, MEK and ERK leading to activation of the transcription factor complex AP-1, which consists of Fos and Jun (28). The NF- $\kappa$ B pathway is blocked in resting T cells, as NF- $\kappa$ B transcription factors, such as p50 and p65, are associated with inhibitors of NF- $\kappa$ B (I $\kappa$ B) that prevent migration to the nucleus. Upon TCR stimulation, PKC $\theta$  activates the I $\kappa$ B kinase (IKK), which induces degradation of I $\kappa$ B followed by translocation of NF- $\kappa$ B transcription factors to the nucleus (29,30). The MAPK/ERK and NF- $\kappa$ B pathways are also triggered through co-receptor CD28-mediated signaling (31,32). Additionally, CD28 initiates the PI3K/AKT signaling pathway. The phosphoinositide 3-kinase (PI3K) binds to the phosphorylated cytoplasmic tail of CD28, followed by recruitment and phosphorylation of the serine/threonine kinase AKT (33). The relative contribution of the TCR vs its coreceptors in the initiation of the PI3K/AKT signaling pathway remains unresolved (34). AKT is best known for its role in cell survival and growth by binding various substrates. The anti-apoptotic effect of AKT is the result of binding pro-apoptotic proteins directly, such as BAD, or the transcription factors that initiate transcription of pro-apoptotic genes, such as FOXO (35). AKT promotes cell growth through activation of the mammalian target of rapamycin (mTOR). Additionally, AKT directly interacts with the NF- $\kappa$ B pathway by phosphorylating IKK (36). Ultimately, all TCR- and CD28-initiated signaling pathways result in transcription of genes involved in cytokine production, differentiation and proliferation of effector T cells. One of these cytokines is IL-2, which plays an important role in enhancing activation of T cells. Activated T cells up-regulate expression of the IL-2 receptor and once IL-2 binds to this receptor, multiple signaling pathways are activated, including the MAPK/ERK pathway and the PI3K/AKT signaling pathway (37).

#### 1.1.4 T-cell homeostasis

Homeostatic mechanisms regulate size and composition of the peripheral T-cell pool and maintain total T-cell number throughout life. These mechanisms differ for naïve, effector and memory T-cell populations. Naïve T cells can survive for long periods of time without being exposed to an antigen. However, they require survival signals provided by interleukin-7 (IL-7) and TCR interaction with spMHC molecules on APCs (Figure 1-4) (38). Naïve T cells compete for these survival signals based on the limited availability of cytokines and specific spMHC molecules. Several models have been proposed that aim to explain how these survival signals regulate size and diversity of the naïve T-cell pool. Some studies suggested that T cells with TCRs of the same peptide specificity compete with each other for access to the same spMHC molecules (intraclonal competition), whereas T cells with a different specificity are unaffected (39,40). Others proposed competition between T cells of different specificities as a mechanism for maintaining T-cell diversity (interclonal competition) that is either based on TCR promiscuity, TCR affinity and/or the ability to respond to other survival signals, such as cytokines, upon TCR interaction with spMHC molecules (41–43). Additionally, it was shown that mature TCR polyclonal, but not TCR monoclonal T cells are resistant to oncogene-induced transformation, suggesting a role of clonal competition in suppression of malignant outgrowth (44,45).

Upon activation, clonal expansion of antigen specific T cells is essential to generate a sufficient number of effector T cells to combat infection. Once a particular threat is eliminated, the large population of reactive T cells is not required any longer. Therefore, apoptosis is directly or indirectly induced in these cells through multiple mechanisms (Figure 1-4). An indirect mechanism is the withdrawal of survival signals such as co-stimulators and cytokines, resulting in a loss of anti-apoptotic gene expression and death by neglect (46,47). Regulatory mechanisms and components that actively terminate T-cell responses include activation-induced cell death (AICD), expression of cytotoxic T lymphocyte antigen 4 (CTLA-4) and the effect of Tregs. Repeated stimulation of the TCR triggers AICD by mediating the expression of the death receptor Fas (CD95) and its ligand FasL (48). Activated T cells also start to express CTLA-4, a second co-receptor besides CD28, that can bind the co-stimulatory molecules CD80 and CD86. Upon binding, CTLA-4 inhibits TCR downstream signaling, thereby blocking IL-2 production (49). Treg function is based on direct cell contact through binding of CTLA-4 on Tregs to CD80/CD86 on effector T cells,

the production of immunosuppressive cytokines, such as transforming growth factor- $\beta$ 1 (TGF- $\beta$ 1) and IL-10, as well as granzyme- and perforin-mediated cytotoxicity (50).

**Figure 1-4: Homeostatic mechanisms during an immune response**

Naïve T cells require IL-7 and TCR interaction with spMHC molecules for survival. Upon antigen exposure, activated T cells differentiate and expand into a large population of effector T cells. After clearance of an immune response, loss of survival signals and regulatory mechanism, such as AICD, CTLA-4 expression and immunosuppressive Tregs, induce apoptosis in most effector T cells to turn the immune system back to a responsive state. The remaining memory T cells are kept alive through cytokine signaling induced by IL-7 and IL-15. Adapted from Parijs et al (51).

The mechanisms that control survival and homeostasis of the remaining memory T cells in the absence of antigen stimulus are less well studied. Memory T cells seem to rely on survival signals mediated by the cytokines IL-7 and IL-15 (52–54). Thereby they compete with naïve T cells for the same resources. It remains controversial whether they require TCR-MHC interactions for survival as well (55–58).

## **1.2 Leukemia and Lymphoma**

Malignant transformation of lymphocytes results in the development of leukemias and lymphomas. B- and T-cell malignancies can be divided into precursor B- and T-lymphoid neoplasms, mature neoplasms of B-, T-, and NK-cell lineage, and apart from these Non-Hodgkin Lymphomas, the category of Hodgkin lymphoma (59). The vast majority of lymphomas arise from B cells, as they are more susceptible to accumulate secondary mutations during their development than do T cells. Error-prone mechanisms like somatic hypermutation and immunoglobulin class switch recombination are necessary to generate a diverse antibody repertoire in B cells, but contribute significantly to lymphomagenesis (60,61).

### **1.2.1 Peripheral T-cell leukemia/lymphoma**

Peripheral or mature T-cell leukemias/lymphomas (PTCL/MTCL) account for 5-10% of all Non-Hodgkin lymphomas and are often associated with a very poor prognosis (62). The World Health Organization (WHO) classifies these neoplasms based on their clinical presentation into primarily nodal, extranodal, cutaneous, and leukemic malignancies (59). These entities are heterogeneous in their clinico-pathologic presentation. Given their infrequent incidence, they represent a considerable diagnostic challenge. Generally, there is a high demand for better treatments in PTCL, as standard therapies show poor responses in these patients (63).

### **1.2.2 T-cell prolymphocytic leukemia (T-PLL)**

#### **1.2.2.1 Characteristics of T-PLL**

T-cell prolymphocytic leukemia (T-PLL) represents the most frequent T-cell leukemia and incidences are estimated to be around 0.6 per million (64–66). Malignant T lymphocytes in T-PLL involve the peripheral blood (PB), LNs, BM, liver, spleen, and skin (59). Consequently, T-PLL patients commonly present with splenomegaly and elevated lymphocyte counts, and less frequently with lymphadenopathy, hepatomegaly, skin lesions, or serous effusions (67). T-PLL cells usually express the pan-T cell antigens CD2, CD3, CD5, and CD7 (68). The expression of CD4 and CD8 is variable. The most common

immunophenotype is CD4+/CD8- (60%), while cases with a CD4+/CD8+ (25%) and CD4-/CD8+ (15%) phenotype occur less frequent (68). Most T-PLL cells are morphologically characterized as medium-sized pro-lymphocytes with a single prominent nucleoli, basophilic cytoplasm, and cytoplasmic blebs (68). The nuclei are usually round to oval, but an irregular cerebriform shape is observed in less common variants of T-PLL as well. Molecular studies revealed two characteristic genetic aberrations involving chromosome 14. Most T-PLL cells carry either chromosomal inversion  $inv(14)(q11;q32)$  or translocation  $t(14;14)(q11;q32)$  (69). This leads in both scenario to juxtaposition of the T-cell leukemia 1 (TCL1A) gene locus at 14q32.1 to TCR $\alpha/\delta$  regulatory elements (70). Consequently, overexpression of the TCL1A protein is observed in 70-80% T-PLL cases and is a hallmark of this entity (65,66,71–74). In 20% of patients the TCL1 family member mature T-cell proliferation 1 (MTCP1) is activated due to translocation  $t(X;14)(q28;q11)$  (68). While genetic abnormalities involving the TCL1 locus are regarded as initial transforming events, additional alterations, like those on chromosomes 11q (involving the tumor suppressor ataxia telangiectasia mutated (ATM)) or involving 8q are frequently observed as well (75,76).

#### **1.2.2.2 T-cell receptor expression in T-PLL**

The TCR is essential for normal T-cell survival and function. Transformed T cells of the different PTCL entities show diverse patterns of TCR expression and signaling activity, thereby suggesting a role in tumorigenesis (77). In T-PLL, most tumor cells express and signal through the TCR (65,74). TCR expression is associated with poorer patient survival compared to cases lacking TCR expression (Figure 1-5A) (74). TCL1A overexpression is a molecular hallmark for T-PLL and the result of chromosomal rearrangement involving TCR $\alpha/\delta$  enhancer elements. Similar to TCR expression, TCL1A+ T-PLL cases correlate with poor outcome (Figure 1-5B). T-PLL cells with high expression of TCL1A have shown increased proliferation and AKT activation upon TCR engagement compared to tumor cells with low or absent TCL1A expression (74). A preferential usage of TCR-V $\beta$  families, that would suggest an antigenic drive, has not been observed for this entity so far (78,79).

**Figure 1-5: Correlation of TCR and TCL1A expression with patient survival in T-PLL**  
 In T-PLL patients, expression of a surface TCR (A) and TCL1A (B) correlate with poor survival compared to cases lacking respective expression. Adapted from Herling et al (74).

### 1.2.2.3 Murine models for T-PLL

Murine models are widely used to study human cancer. Given the limited availability of primary material of rare entities like T-PLL, murine models are especially valuable to gain a better understanding of their pathogenesis. As T-PLL is characterized by overexpression of TCL1A, transgenic mice expressing TCL1A under a T cell-specific Lck promoter developed a monoclonal T-PLL-like disease between 15 and 20 months of age (80). These mice showed enlarged spleens, LNs and thymi, and elevated white blood counts (WBCs) (Figure 1-6E). In contrast to human T-PLL, malignant cells in these mice had a CD4<sup>-</sup>CD8<sup>+</sup> immunophenotype. Another T-PLL model is the MTCP1<sup>p13</sup>-transgenic mouse. The p13 oncogenic isoform of MTCP1 is expressed under a CD2 promoter in this model and induced a T-PLL-like disease to become clinically overt at 18-20 months of age (81). These mice frequently presented with enlarged spleens and lymphocytosis (Figure 1-6A-D). In most cases, leukemic cells showed a CD4<sup>-</sup>CD8<sup>+</sup> immunophenotype.

**Figure 1-6: T-PLL-like disease in mice**  
*MTCP1 (A-D) and TCL1A (E) transgenic mice develop a T-PLL like disease with enlarged spleens (A, E). T-cell prolymphocytes are found in the blood (B), spleen (C) and liver (D). Adapted from Virgilio et al and Gritti et al (80,81)*

### 1.3 The T-cell leukemia/lymphoma 1 (TCL1A) family

The members of the T-cell leukemia/lymphoma 1 (TCL1A) family were first identified by their involvement in specific chromosomal rearrangements in mature T-cell malignancies. In humans this family consists of 3 genes: TCL1A, MTCP1, and TCL1B (also called TML1) (82–85). In mice, in addition to the 2 homologues of each TCL1A and MTCP1, there are five genes homologous to human TCL1B (Tcl1b1, Tcl1b2, Tcl1b3, Tcl1b4, Tcl1b5)(84).

#### 1.3.1 TCL1A

##### 1.3.1.1 Expression pattern of TCL1A in healthy tissues

The TCL1A gene encodes a 14kDa non-enzymatic protein with a closed antiparallel  $\beta$ -barrel structure, consisting of eight  $\beta$ -strands with a hydrophobic core (86,87). Structural studies revealed that the TCL1A protein contains a homodimerization domain (87).

In mice, TCL1A was shown to be expressed in embryonic stem cells and in fetal tissue, namely in liver, yolk sac, thymus and BM (88,89). In adult mouse tissue, TCL1A expression was found in spleen, thymus, BM, PB lymphocytes and testis, suggesting a functional role in lymphopoiesis (84,88,90). Murine TCL1A expression was detected in T cells at the DN4 and

DP stage (see section 1.1.1) and in B cells during all developmental stages in the BM, as well as in all subpopulations of the spleen and LN (90).

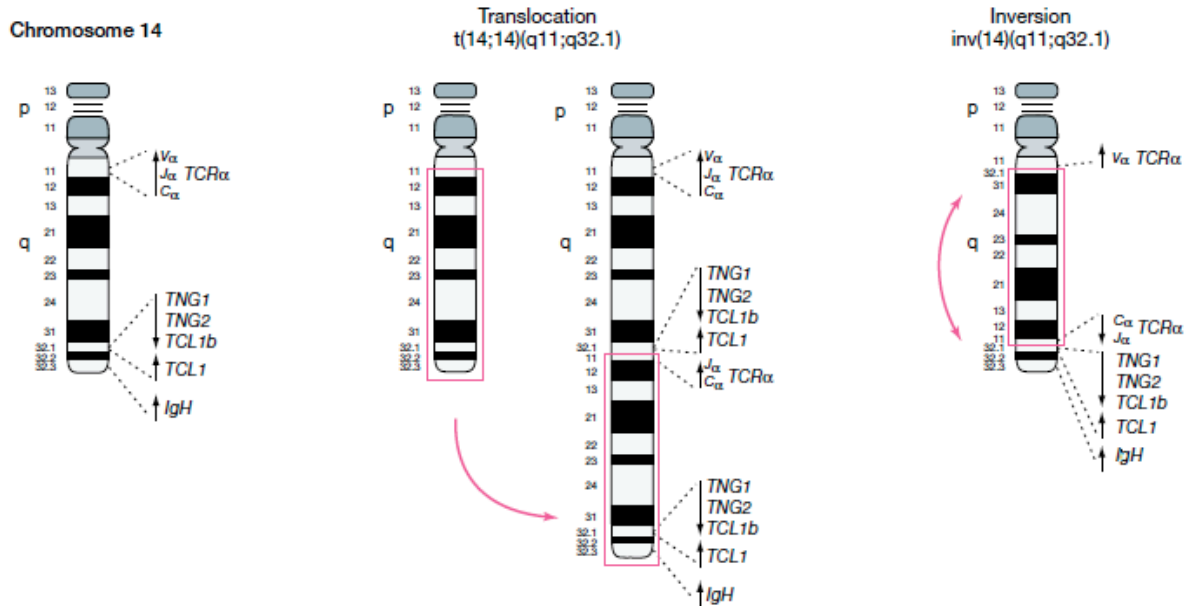

In human fetal tissues, TCL1A expression was detectable in liver, kidney, thymus and lung (91). In human adult tissues, it was found in spleen, LN, BM, thymus, and tonsil (91). Sorted B-cell populations from fetal BM showed TCL1A expression at the pro-B-cell, pre-B-cell and immature B-cell stage (70). High TCL1A transcript levels were also observed in naïve PB B cells and CD5<sup>+</sup> B cells sorted from healthy adult donors (92), whereas others reported TCL1A expression in PB lymphocytes only upon stimulation (70). Sorted thymocyte populations expressed TCL1A at the DN stage, but not at the DP stage (70). Additionally, TCL1 expression was found in plasmacytoid dendritic cells in reactive human LNs (93). The expression pattern of TCL1A in humans showed high similarities with the one in mice. It is therefore most likely that TCL1A plays a similar role in human embryonic development and early T- and B-cell development.

### **1.3.1.2 Oncogenic properties of TCL1A**

TCL1A was first described based on its aberrant expression in T-cell malignancies (85). In humans, TCL1A overexpression is detected in many mature B-cell lymphomas, in the majority of T-PLL, in T-cell leukemias arising in patients with the condition of ataxia telangiectasia (A-T), blastic plasmacytoid dendritic cell neoplasms, germ cell tumors, hepatocellular carcinoma, and adenocarcinoma of the esophagus (65,70,93–100). TCL1A expression has also been described for various human lymphoma/leukemia cell lines: Burkitt's lymphoma cell lines Raji, Daudi, CA-46, P3HR-1 and AKUA; EBV transformed lymphoblastic cell lines Ado-1701 and Ado-2199; acute lymphoblastic cell lines 697, ALL380, ALL-1 and BV173; T-lymphoblastic leukemia/lymphoma cell line Sup-T11 (70,84,91).

In mice, the TCL1 locus is found on chromosome 12, whereas in humans the TCL1 locus is located on chromosome 14, band q32.1 (101). In humans, rearrangements involving the TCL1 locus are commonly found in T-PLL (see section 1.2.2.1) and lead to abnormal expression of TCL1A. The TCL1 locus rearranges either with the TCR $\alpha/\delta$  locus on chromosome 14 by inversion *inv*(14)(q11;q32) or translocation *t*(14;14)(q11;q32) (Figure 1-7), or with the TCR $\beta$  locus on chromosome 7 by translocation *t*(7;14)(q35;q32) (101). In all of these scenarios the TCL1 locus is juxtaposed to TCR enhancer elements, most likely

causing aberrant (prolonged) activation of TCL1A (101) as opposed to its physiological post-thymic silencing.

**Figure 1-7: Chromosomal rearrangements involving the TCL1 locus**

The TCL1 locus is located on chromosome 14, band q32.1 (left). Chromosomal rearrangements that lead to overexpression in mature T-cell leukemias involve the TCRα/δ locus on chromosome 14, band q11. These rearrangements juxtapose TCL1A to the TCR locus either by translocation  $t(14;14)(q11;q32)$  (middle) or inversion  $inv(14)(q11;q32)$  (right). Adapted from Pekarsky et al (102).

The majority of cases of human chronic lymphocytic leukemia (CLL) are associated with TCL1A expression as well (103). However, TCL1A expression levels vary between these patients. High TCL1A expression was associated with an unmutated IGHV gene status, high ZAP-70 expression, and chromosome 11q22–23 deletions in these patients (103). In contrast to T-PLL, CLL patient samples do not show rearrangements involving the TCL1 locus (104). Alternative mechanisms leading to abnormal expression of TCL1A in B-cell malignancies have been proposed, including those that involve transcriptional activation by Sp1, external signals provided by cells in the microenvironment that are either TCL1A suppressive (T cell-mediated) or activating (stromal cell-mediated), and decreased levels of TCL1A-targeting micro-RNAs (103,105–109). Gene expression profiling revealed comparable TCL1A transcript levels in CLL cells and mature B-cell populations (naïve B cells and CD5<sup>+</sup> B cells) from healthy donors, suggesting that CLL cells either inherited or adopted high TCL1 expression from their histogenetically related healthy B-cell populations (92).

As described in section 1.2.2.3, overexpression of TCL1A in T cells of transgenic mice causes cellular transformation, thereby providing functional proof for its oncogenic potential (80). Although originally identified as an oncogene in T cells, TCL1A also plays a role in the transformation of mature B cells. Transgenic mice that expressed TCL1A in B and T cells predominantly developed Burkitt-like lymphoma (BLL) and diffuse large B-cell lymphoma (DLBCL) starting at the age of 4 months (110). These mice presented with variable splenomegaly, lymphadenopathy, and macroscopic lesions of the liver, lung, kidney, and intestines. Tumor cells in most cases were IgM<sup>+</sup>B220<sup>lo</sup>CD5<sup>lo</sup> B cells. Splenocytes isolated from these transgenic mice before tumor development showed prolonged cell survival and increased proliferation compared to control mice. When TCL1A expression was driven by a B cell-specific IgH E $\mu$  enhancer element, transgenic mice developed a CLL-like malignancy (111). These mice showed enlarged spleens, LNs and livers associated with elevated WBCs. Tumor cells were characterized as CD5<sup>+</sup>IgM<sup>+</sup>. This system has been widely used as a model for human CLL (112).

### **1.3.1.3 Functional aspects of TCL1A**

The functional role of TCL1A as extrapolated by its expression patterns and as identified by its interaction partners and subcellular localization, is most likely determined in a cell and tissue specific manner. In embryonic stem cells, TCL1A enhanced proliferation and suppressed differentiation, implicating a functional role in self-renewal and maintenance of pluripotency (89,113–115). Its importance in embryonic development was also supported by studies of TCL1A deficient mice that showed reduced fertility in females caused by an impaired pre-implantation embryo development (95). TCL1A seems to function similarly in adult stem cells of the hair follicle as these cells showed reduced proliferation and loss of the stem-cell marker CD34 in TCL1A deficient mice (116). Loss of TCL1A also led to a significant decrease in the number of pre-B cells, immature B cells and thymocytes at the DN and DP stages, as well as splenic T-and B-cell populations (90).

The first protein that was identified to co-precipitate and specifically (directly) interact with TCL1A in human B-cell lines is the serine/threonine kinase AKT (117). The PI3K/AKT signaling pathway has been described in section 1.1.3 as one of the major downstream signaling pathways involved in T-cell activation. TCL1A was described to interact with AKT at the membrane by binding to its N-terminal pleckstrin homology (PH) domain, a functional

domain that mediates protein-protein and protein-lipid interactions (117,118). Aberrant AKT activation by TCL1A resulted in augmented phosphorylation of downstream AKT target proteins promoting cellular survival and proliferation (117,119,120).

Moreover, it was described that TCL1A activates the NF- $\kappa$ B pathway by interacting with the transcriptional activator p300, a known co-activator of NF- $\kappa$ B, in the Burkitt's lymphoma cell line Daudi (121). In the same study, they showed that TCL1A also binds the AP-1 components Jun and Fos in the nucleus, thereby inhibiting AP-1 transcriptional activity. In CLL cells, up-regulation of TCL1A was associated with down-modulation of Fos and Jun proteins (107). Although the AP-1 complex was described as an activator of proliferation in section 1.1.3, it is also known to be involved in induction of apoptosis in lymphoid cells after growth factor withdrawal (122).

Another interaction partner of TCL1A is the serine/threonine protein kinase ATM that normally induces cell cycle arrest, DNA repair and/or apoptosis upon DNA damage (123,124). This interaction resulted in the activation of NF- $\kappa$ B by inducing degradation of I $\kappa$ B, allowing translocation of NF- $\kappa$ B transcription factors to the nucleus. Similar to AP-1, NF- $\kappa$ B transcription factors are required for T-cell activation (see section 1.1.3), but have been associated with initiation of apoptosis in response to cellular stress (125).

AKT and ATM modulate important cellular signaling pathways and deregulation of these genes alone results in cellular transformation. Transgenic mice expressing myristoylated or constitutively active AKT developed lymphoblastic lymphomas (126). These tumors also arose in ATM-deficient mice (127). The oncogenic function of TCL1A is therefore mostly likely based on the combined deregulation of several different pathways, as it is associated with induction of mature T- and B-cell malignancies.

As described before, the majority of T-PLL cells express a functional TCR (see 1.2.2.2). Engagement of the TCR in these cells led to TCL1A and AKT recruitment to the cell membrane (Figure 1-8A) and formation of TCR-signalosomes with other signaling kinases, such as Lck (Figure 1-8B) (74). Eventually TCL1A and AKT co-localized to the nucleus (74). Similarly, B-cell receptor (BCR) engagement in TCL1 expressing CLL cells led to recruitment of TCL1A and AKT to BCR membrane complexes (128). In mice, abnormal TCL1A expression enhanced cytokine secretion and proliferation of mature T cells upon TCR or pharmacologic activation through enhanced phosphorylation of PKC $\theta$  and ERK (71). This is in contrast with a study of activated human T cells that showed impaired PKC $\theta$  and ERK phosphorylation in the presence of TCL1A leading to an inhibition of AICD (129). However, it is unclear how TCL1A interferes with these signaling molecules.

The previously described interactions of TCL1A with other proteins were detected in the cytosol (AKT, p300, ATM) and the nucleus (AKT, Jun, Fos) (74,86,119,121,123). Thus, TCL1A protein localization is not restricted to a particular cellular compartment, but rather determines its function through compartment-specific interaction partners.

**Figure 1-8: TCL1A recruitment to the membrane upon TCR engagement in T-PLL cells**  
 (A) In unstimulated T-PLL cells, TCL1A and AKT are found in the cytosol without co-localizing (ctr, top panel). However, upon TCR stimulation with CD3/28 beads, TCL1A and AKT co-localize at the cell membrane (middle panel). (B) Continuous TCR engagement leads to accumulation of TCL1A and AKT in distinct membrane complexes (top and middle panel) together with the signaling kinase Lck (bottom panel). Adapted from Herling et al (74).

### 1.3.2 MTCP1

MTCP1 was discovered by involvement in t(X;14) translocations in two mature T-cell proliferations (82). Normally, the gene is localized on Xq28 (82) and encodes two different proteins: the mitochondrial protein p8 (130) and the protein p13 (131). These proteins share no similarity with each other, but the p13 isoform shows 39% amino acid identity with TCL1A and 95% identity with murine p13Mtcp1 (131). As only the p13MTCP1 protein is part of the TCL1 family, it is generally referred to as MTCP1 in this thesis. Although this 13kDA protein lacks a dimerization surface, it has been shown that it interacts with AKT ( $K_d$  of  $537\mu\text{M}$ ), however, with much lower affinity than TCL1A ( $K_d$  of  $5.7\mu\text{M}$ ) (87,117,132).

The fact that MTCP1 is oncogenic suggests other relevant executioners than / in addition to AKT or that it likely requires additional bridging molecules (132). Other interaction partners have not been described for this protein. In mice, normal Mtcp1 expression is found in early fetal tissues (liver, yolk sac); in liver, kidney and spleen in adult tissue (88) and in mature T cells after infection (133). The human MTCP1 oncoprotein showed low expression in most tissues (82) and was not detected in normal resting or activated lymphocytes (131). Therefore, MTCP1 expression was limited to mature T-cell proliferations with t(X;14) translocations in humans (82,131). Transgenic mice for human MTCP1 developed mature T-cell leukemia similar to human T-PLL after a long latency period (>15months) (81), thereby directly demonstrating its oncogenic properties. Sick mice often presented with splenomegaly and elevated WBC. Further examination revealed infiltrations of lymphoid cells into all lymphoid organs, liver and lungs. In 23 cases tumor cells were phenotypically characterized as CD3<sup>+</sup>, CD8<sup>+</sup>, CD4<sup>-</sup>, CD25<sup>-</sup>, B220<sup>-</sup> and in one case as CD3<sup>+</sup>, CD4<sup>+</sup>, CD8<sup>-</sup>, CD25<sup>-</sup>, B220<sup>-</sup>.

### **1.3.3 TCL1B/TML1**

Human TCL1B/TML1 (TCL1A/MTCP1-like 1) is the third member of the TCL1 family and was identified by screening the frequently rearranged region on chromosome 14q32.1 for affected genes other than TCL1A (83,91). The amino acid sequence of TML1 shows over 30% identity and 60% similarity with TCL1A and MTCP1, and has a 14 amino acid insertion compared to human TCL1A (84,91). Similar to MTCP1, this 15kDA protein does not contain a dimerization domain and interacts with AKT with lower affinity than TCL1A (83,117). Human TML1 is normally expressed in fetal liver, kidney, heart, spleen and thymus (91). In adult tissue very low expression levels are found in placenta, testis, kidney, spleen, LNs, tonsil and PB lymphocytes (83,91). In human cancer cell lines, TML1 expression is detected in Burkitt's lymphomas, EBV-transformed lymphoblastoid B-cell lines and T-cell leukemia with a translocation at 14q32.1 (83,91). In mice, five genes (Tcl1b1-Tcl1b5) were found in the TCL1 locus that are homologous to human TML1 (84). The five proteins showed a 30-40% similarity to human TML1. Expression was high in mouse oocytes and two-cell embryos, but low in adult tissues and lymphoid cell lines (84). TML1 is the least studied family member and it is unknown whether it has oncogenic properties by itself.

## 1.4 Objectives

Deregulated expression of the TCL1 family genes TCL1A, MTCP1 and TML1 was first described in T-cell malignancies. In transgenic mice, overexpression of TCL1A and MTCP1 causes outgrowth of mature T- and B-cell tumors. Different promoters were used in these studies to target gene expression to T and/or B cells, making it difficult to compare oncogenic properties of the two family members directly. Studies describing the oncogenic potential of TML1 in vivo have not been described yet. Therefore, the first aim of this thesis is to determine and characterize tumorigenicity of the TCL1 family genes in vivo by using gamma-retroviral vectors to introduce human TCL1A, MTCP1 and TML1 into HSC/hematopoietic progenitor cells (HPC) of wild type mice that are transplanted into wild type recipients. TCL1A is expressed in the cytoplasm and the nucleus, thereby targeting different signaling molecules. To examine if enforced TCL1A localization influences its downstream effects, allowing inferences on a preferred/differential oncogenic potential, a myristoylated (membrane localizing) variant (myr-TCL1A) and a nuclear-site directed variant (nls-TCL1A) of the TCL1A construct are additionally used in the previously described mouse model.

TCL1A overexpression is detected in the majority of T-PLL. These tumor cells usually express a TCR. The oncogenic function of TCL1A is based on the modulation of various signaling pathways by interacting with key signaling molecules, especially in the context of TCR activation. This suggests a cooperation of TCL1A and TCR signals in the development of T-PLL. However, it is unknown how and to what extent TCR signaling plays a role in TCL1-driven lymphomagenesis/leukemogenesis. The second part of this thesis aims to understand the combined action of TCR signals and TCL1A oncogenes in perturbation of T-cell homeostasis and in cellular transformation. Therefore, TCR-transgenic monoclonal OT-1 T cells are retrovirally transduced with vectors encoding TCL1A, myr-TCL1A, and nls-TCL1A, and then transplanted into RAG1-deficient ( $RAG1^{-/-}$ ) mice. Recipient mice are injected with the OVA peptide SIINFEKL every two weeks to specifically stimulate the TCR of OT-1 donor cells and to study the impact of repeated TCR engagement on TCL1-driven transformation.

## 2. Materials and Methods

### 2.1 Materials

#### 2.1.1 Antibodies

Antibody Specificity	Clone	Conjugate	Reactivity	Manufacturer	Application
CD3 $\epsilon$	145-2C11	Purified	Mouse	BD, Franklin Lakes, New Jersey, USA	T-cell stimulation
CD3 $\epsilon$	145-2C11	PE	Mouse	Miltenyi Biotec, Bergisch Gladbach, Germany	FC

### 2.1.3 Buffer and Solution Compositions

Buffer	Composition
Annealing buffer (5x)	0.5 M Tris (pH 7.4-7.5), 0.35 M MgCl <sub>2</sub>
Bovine serum albumine BSA (10%)	10% (m/v) BSA in ddH <sub>2</sub> O, sterile-filtered and stored at 4°C
Bind and wash buffer (2x)	10mM Tris (pH 7.5), 1mM EDTA, 2M NaCl
BSA/PBS 10% stock solution	10g BSA in 100ml PBS

Chloroquine	25µM in ddH <sub>2</sub> O, sterile-filtered and stored at 4°C
FACS Fixation Solution	2% Paraformaldehyde in PBS
FACS-buffer	PBS, 2% FCS, 0.05% NaN <sub>3</sub> stored at 4°C
HEPES (2x)	281mM NaCl, 100mM HEPES, 5mM Na <sub>2</sub> HPO <sub>4</sub> in ddH <sub>2</sub> O, pH 7.0, stored at -20°C
MSA blocking solution 0.1%	25mg MSA in 25ml PBS, sterile filtered and stored at 4°C
PBS-T	0.05% Tween-20 in PBS
SDS, 10%	25g SDS in 250ml ddH <sub>2</sub> O
SDS loading buffer, 6x	60% (v/v) glycerin, 18% (w/v) SDS, 0.3% (v/v) bromophenol blue, 600mM Tris-HCl, 12% (v/v) β-mercaptoethanol
Transfer/Blotting Buffer	20% (v/v) Methanol, 10% (v/v) TOWBIN Buffer
TOWBIN Buffer	144g Glycin, 30.29g Tris, 250mg SDS

**Table 2-2: Buffer Compositions**

## 2.1.4 Chemicals and Reagents

Chemical/Reagent	Manufacturer
4-(2-Hydroxyethyl)piperazine-1-ethanesulfonic acid (HEPES)	Sigma-Aldrich, St.Louis, Missouri, USA
Ampicillin, sodium salt	Roth, Karlsruhe, Germany
Amplification buffer (10x) (Buffer A)	Segetic, Borken, Germany
β-mercaptoethanol	Gibco, Life Technologies, Darmstadt, Germany
BSA (bovine serum albumin)	Sigma-Aldrich, St.Louis, Missouri, USA
Bromophenol Blue	Sigma-Aldrich, St.Louis, Missouri, USA
CaCl <sub>2</sub>	Merck, Darmstadt, Germany
CellTrace Violet Cell Proliferation Kit	Life Technologies, Darmstadt, Germany
Chloroquine	Sigma-Aldrich, St.Louis, Missouri, USA
Dimethyl sulfoxide (DMSO)	Serva, Heidelberg, Germany
Distilled Water	Gibco, Life Technologies, Darmstadt, Germany
D-Luciferin	PerkinElmer, Waltham, Massachusetts, USA
DNA ExitusPlus IF	AppliChem, Darmstadt, Germany
DNA Ladder (100bp, 1kb)	New England Biolabs, Ipswich, Massachusetts, USA

DNA loading dye (6x)	New England Biolabs, Ipswich, Massachusetts, USA
dNTPs (10mM)	Fermentas, Thermo Fisher Scientific, Waltham, Massachusetts, USA
Dulbecco's Modified Eagle Medium (DMEM)	Gibco, Life Technologies, Darmstadt, Germany
Dulbecco's Phosphate Buffered Saline (PBS)	PAA Laboratories, Pasching, Austria
Ethylenediaminetetraacetic acid (EDTA)	Sigma-Aldrich, St.Louis, Missouri, USA
Ethanol	Roth, Karlsruhe, Germany
Ethidium bromide	Bio-Rad, Hercules, California, USA
Extensor High Fidelity Master Mix	ABgene, Thermo Fisher Scientific, Waltham, Massachusetts, USA
FcR Blocking Reagent, mouse	Miltenyi Biotec, Bergisch Gladbach, Germany
Fetal bovine serum (FBS)	PAA Laboratories, Pasching, Austria
Freund's Adjuvant, Incomplete (IFA)	Sigma-Aldrich, St.Louis, Missouri, USA
Formaldehyde (37%)	Roth, Karlsruhe, Germany
Glycerol	Roth, Karlsruhe, Germany
Glycin	Sigma-Aldrich, St.Louis, Missouri, USA
Hanks balanced salt solution (HBSS)	Sigma-Aldrich, St.Louis, Missouri, USA
Human interleukin-2 (IL-2) (10000U/ml)	Novartis, Basel, Switzerland
Hydrochloride (HCl)	Merck, Darmstadt, Germany
Isopropanol	Merck, Darmstadt, Germany
Iscove's Modified Dulbecco's Medium (IMDM)	Gibco, Life Technologies, Darmstadt, Germany
Isoflurane	Abbvie, Ludwigshafen, Germany
Kanamycin-sulfate	Roth, Karlsruhe, Germany
LB Broth	Roth, Karlsruhe, Germany
LE Agarose	Bio-Rad, Hercules, California, USA
L-Glutamine	Gibco, Life Technologies, Darmstadt, Germany
Lyse/Fix Buffer (5X)	BD, Franklin Lakes, New Jersey, USA
Lysing Buffer (10x)	BD, Franklin Lakes, New Jersey, USA
Methanol	Roth, Karlsruhe, Germany
Magnesium Chloride MgCl <sub>2</sub>	Merck, Darmstadt, Germany
Mouse Serum Albumin (MSA)	EMD Millipore, Billerica, USA

Non-essential amino acids (NEAA)	Gibco, Life Technologies, Darmstadt, Germany
NuPAGE MES SDS Running Buffer (20X)	Life Technologies, Darmstadt, Germany
NuPAGE Novex 4-12% Bis-Tris Protein Gels, 1.0 mm, 15 well	Life Technologies, Darmstadt, Germany
NuPAGE Novex 12% Bis-Tris Protein Gels, 1.0 mm, 15 well	Life Technologies, Darmstadt, Germany
OVA (257-264)	Eurogentec, Seraing, Belgium
PCR Primers	Eurofins MWG Operon, Ebersberg, Germany
Penicillin/Streptavidin	Gibco, Life Technologies, Darmstadt, Germany
Perm Buffer III	BD, Franklin Lakes, New Jersey, USA
Phosphatase Inhibitor Cocktail Tablets, PhosSTOP	Roche Diagnostics, Mannheim, Germany
Phusion High-Fidelity DNA Polymerase	Finnzymes, New England Biolabs, Ipswich, Massachusetts, USA
Protease Inhibitor Cocktail Tablets, cOmplete Mini	Roche Diagnostics, Mannheim, Germany
Retronectin	Takara/Clontech, Mountain View, California, USA
Restriction Endonucleases	New England Biolabs, Ipswich, Massachusetts, USA
Roswell Park Memorial Institute (RPMI) 1640	Gibco, Life Technologies, Darmstadt, Germany
Roti-Block	Roth, Karlsruhe, Germany
RNase (DNase free)	Roche, Basel, Switzerland
S.O.C. medium	Invitrogen, Life Technologies, Darmstadt, Germany
Sodium Chloride (NaCl)	Roth, Karlsruhe, Germany
Sodium Dodecyl Sulfate (SDS)	AppliChem, Darmstadt, Germany
Sodium Fluoride (NaF)	Fluka, Sigma-Aldrich, St.Louis, Missouri, USA
Sodium Hydroxide (NaOH)	Merck, Darmstadt, Germany
Sodium Orthovanadate (Na <sub>3</sub> VO <sub>4</sub> )	Sigma-Aldrich, St.Louis, Missouri, USA
Sodium Phosphate (Na <sub>3</sub> PO <sub>4</sub> )	Sigma-Aldrich, St.Louis, Missouri, USA
Sodium Pyruvate	Gibco, Life Technologies, Darmstadt, Germany
StemSpan SFEM	STEMCELL Technologies, Vancouver, Canada
T4 DNA Ligase	New England Biolabs, Ipswich, Massachusetts, USA
Taq Polymerase	Segetic, Borken, Germany
Tris-(Hydroxymethyl)-Aminomethane (Tris)	AppliChem, Darmstadt, Germany
Tris-Hydrogen Chloride Buffer (Tris-HCl)	Bio-Rad, Hercules, California, USA

Trypan Blue	Sigma-Aldrich, St.Louis, Missouri, USA
Trypsin-EDTA solution (0.05%)	Invitrogen, Life Technologies, Darmstadt, Germany
Tween-20	Merck, Darmstadt, Germany

**Table 2-3: Chemicals and Reagents**

### 2.1.5 Commercial Kits

<b>Kit</b>	<b>Manufacturer</b>
Calcium Phosphat Transfektion Kit	Sigma-Aldrich, St.Louis, Missouri, USA
DNeasy Blood & Tissue Kit	Qiagen, Hilden, Germany
Dynabeads M-280 Streptavidin	Invitrogen, Life Technologies, Darmstadt, Germany
Dynabeads M-450 Epoxy	Invitrogen, Life Technologies, Darmstadt, Germany
ECL-Plus Western Blot Kit	Amersham, GE Healthcare Life Sciences, Freiburg, Germany
Fix&Perm Cell Permeabilization Kit	Life Technologies, Darmstadt, Germany
Gel and PCR Clean-up	NucleoSpin, Macherey-Nagel, Düren, Germany
Lineage Cell Depletion Kit	Miltenyi Biotec, Bergisch Gladbach, Germany
MinElute Reaction Cleanup Kit	Qiagen, Hilden, Germany
peqGold Cycle Pure Kit	peqLab, Erlangen, Germany
Qiagen Plasmid Maxi Kit	Qiagen, Hilden, Germany
QIAquick PCR Purification Kit	Qiagen, Hilden, Germany
RNAlater	Qiagen, Hilden, Germany
RNeasy Mini Kit	Qiagen, Hilden, Germany
TOPO TA Cloning Kit	Invitrogen, Life Technologies, Darmstadt, Germany

**Table 2-4: Commercial Kits**

### 2.1.6 Laboratory Equipment and Instruments

<b>Equipment / Instrument</b>	<b>Manufacturer</b>
Analytical balance, BP61	Sartorius Stedim Biotec, Göttingen, Germany
Autoclave, VX-95	Systec, Wetzlar, Germany
Blotting system, Criterion	Bio-Rad, Hercules, California, USA

Cell freezing container, Mr. Frosty	Nalgene, Thermo Fisher Scientific, Waltham, Massachusetts, USA
Cell Sorter, BD FACSAria II	BD, Franklin Lakes, New Jersey, USA
Centrifuge Heraeus Fresco 21, tabletop	Heraeus, Thermo Fisher Scientific, Waltham, Massachusetts, USA
Centrifuge, tabletop	Hettich, Tuttlingen, Germany
Centrifuge, Biofuge 15R, tabletop	Thermo Fisher Scientific, Waltham, Massachusetts, USA
Centrifuge, Minifuge RF	Heraeus, Thermo Fisher Scientific, Waltham, Massachusetts, USA
Centrifuge Megafuge 1.0R	Heraeus, Thermo Fisher Scientific, Waltham, Massachusetts, USA
Clean bench HERAsafe KS	Thermo Fisher Scientific, Waltham, Massachusetts, USA
CO <sub>2</sub> Incubator HERAccl 150i	Thermo Fisher Scientific, Waltham, Massachusetts, USA
Flow Cytometer, MACS Quant Analyzer	Miltenyi Biotec, Bergisch Gladbach, Germany
Fluorescence Microscope, Axioskop 2	ZEISS, Oberkochen, Germany
Horizontal Electrophoresis Systems	Bio-Rad, Hercules, California, USA
Hot Air Sterilizer, T12	Heraeus, Thermo Fisher Scientific, Waltham, Massachusetts, USA
Imaging System, Fusion-SL	peqLab, Erlangen, Germany
In Vivo Imaging System, IVIS Lumina Series II	PerkinElmer, Waltham, Massachusetts, USA
MACS MultiStand	Miltenyi Biotec, Bergisch Gladbach, Germany
MACS Separators	Miltenyi Biotec, Bergisch Gladbach, Germany
Magnetic Particle Concentrator, MPC-S	Invitrogen, Life Technologies, Darmstadt, Germany
Magnetic Stirrer, RCT basic	IKA, Staufen, Germany
Microplate Reader Infinite M200 Pro	Tecan, Männedorf, Switzerland
Microscope Olympus IX70	Olympus, Tokyo, Japan
Mini-Cell Electrophoresis System, XCell SureLock	Life Tehnologies, Darmstadt, Germany
Nano-Drop ND 1000 spectrometer	peqLab, Erlangen, Germany
pH-Meter	Knick, Berlin, Germany
Pipettes	Eppendorf, Hamburg, Germany
Pipetus	Hirschmann, Eberstadt, Germany
Pipet Stepper	Eppendorf, Hamburg, Germany
Power supply PowerPac	Bio-Rad, Hercules, California, USA
Scil Vet ABC (Animal Blood Counter)	Scil animal care company, Viernheim, Germany

Shaking Incubator	Edmund Bühler LabTec, Hechingen, Germany
Thermal Cycler Mastercycler Pro	Eppendorf, Hamburg, Germany
Thermomixer	Eppendorf, Hamburg, Germany
UV-Lamp	Konrad Benda, Wiesloch, Germany
Vacuum Pump	Integra Biosciences, Fernwald, Germany
Vortex	Roth, Karlsruhe, Germany
Water Bath	GFL, Burgwedel, Germany
XGI-8 anesthesia system	PerkinElmer, Waltham, Massachusetts, USA

**Table 2-5: Laboratory Equipment and Instruments**

### 2.1.7 Laboratory Supplies and Consumables

Supply / Consumable	Manufacturer
Blotting Sandwich Immobilon-P	Merck Millipore, Billerica, Massachusetts, USA
Combitips Advanced (1, 5 and 10ml)	Eppendorf, Hamburg, Germany
Conical Centrifuge Tubes (15 and 50ml)	Greiner Bio-One, Frickenhausen, Germany
C-Chip Disposable Hemocytometer, Neubauer improved	NanoEnTek, Seoul, Korea
Cryogenic Tubes (2ml)	Thermo Fisher Scientific, Waltham, Massachusetts, USA
Filter Cap Cell Culture flasks (25, 75 and 175cm <sup>2</sup> )	Greiner Bio-One, Frickenhausen, Germany
Microvette CB 300 µl, K2 EDTA	Sarstedt, Nümbrecht, Germany
Nitril Gloves	Braun, Melsungen, Germany
Non-tissue culture plates (6 and 24 well)	Falcon, Corning, New York, USA
Pasteur Pipettes	Corning, New York, USA
Petri Dishes	Greiner Bio-One, Frickenhausen, Germany
Pipette tips (10, 100, 200 and 1000µl)	peqLab, Erlangen, Germany
Pipette tips (10, 100, 200 and 1000µl) aerosol-resistant	peqLab, Erlangen, Germany
Polystyrene Round-Bottom Tube (5ml)	Falcon, Corning, New York, USA
Reaction tubes (0.1, 0.2, 1.5 and 2ml)	Eppendorf, Hamburg, Germany
Scalpels	mediware Servoprax, Wesel, Germany
Serological pipettes (2, 5, 10 and 25ml)	Costar, Corning, New York, USA

Sterile cell strainer	BD, Franklin Lakes, New Jersey, USA
Sterile filters (0.22 and 0.45µm)	Merck Millipore, Billerica, Massachusetts, USA
Syringes (5,10 and 20ml)	Braun, Melsungen, Germany
Tissue culture dishes (10cm)	Greiner Bio-One, Frickenhausen, Germany
Tissue culture plates (6, 12, 24 and 96 well)	Costar, Corning, New York, USA
Tube 5ml, 75x12mm, PS	Sarstedt, Nümbrecht, Germany

**Table 2-6: Laboratory Supplies and Consumables**

### 2.1.8 Plasmids and Vectors

Plasmid name	Description	Reference
Eco-env	Expression plasmid for ecotropic envelope protein from MLV	Stitz, J., et al (134)
MP91-EGFP	Retroviral vector with a modified leader region MP91 (MPSV-LTR and MESV-leader), coding for IRES-EGFP with a 5' packaging signal	Schambach, A., et al (135)
MLV gag-pol	Expression plasmid for MLV Gag-Pol with SV40-Promotor	C.Baum (MHH)
MP91-TCL1A-EGFP	Retroviral vector containing human TCL1A-IRES-EGFP.	Cloned for this study.
MP91-myr-TCL1A-EGFP	Retroviral vector coding for human myristoylated (myr) TCL1A-IRES-EGFP.	Cloned for this study.
MP91-nls-TCL1A-EGFP	cDNA for human TCL1A, containing a nuclear localization sequence (nls), cloned into MP91-EGFP.	Cloned for this study.
MP91-MTCP1-EGFP	Retroviral vector coding for human MTCP1-IRES-EGFP.	Cloned for this study.
MP91-TML1-EGFP	Retroviral vector coding for human TML1-IRES-EGFP.	Cloned for this study.
MP91-T-Sapphire-Luc	Retroviral vector coding for T-Sapphire-IRES-Luc.	K.Cornils (University of Hamburg)
MP91-TCL1A-Luc	Retroviral vector coding for human TCL1A-IRES-Luc.	K.Cornils (University of Hamburg)

**Table 2-7: Plasmids and Vectors**

The used retroviral vectors are flanked by 5' and 3' long terminal repeats (LTR), responsible for gene expression, reverse transcription and viral integration. Furthermore, the internal ribosome entry site (IRES) allows co-expression of multiple genes, e.g. a reporter gene and a gene of interest. In the presented model, enhanced green fluorescent protein (EGFP) or firefly luciferase (luc) were used as reporter genes and TCL1 oncogenes were genes of interest. The

Woodchuck hepatitis virus posttranscriptional regulatory element (WPRE) further enhances gene expression. For plasmid maps, see Figure 5-1 in section 5.2.

### 2.1.9 Primary Cells and Cell Lines

Cells	Media	Description
Murine Splenocytes	RPMI 1640 Mouse Special	Isolated from spleen and LNs of OT-1 donor mice.
Murine HSCs/HPCs	StemSpan SFEM complete	Isolated from femur and tibia of B6 SJL donor mice.
HEK 293T	DMEM complete	Human embryonic kidney 293 cells containing the SV40 T-antigen (136).
SC1	DMEM complete	Mouse embryonic fibroblasts (137)
CTLL-2	IMDM CTLL-2	Mouse cytotoxic T-lymphocyte (138)

**Table 2-8: Primary Cells and Cell Lines**

### 2.1.10 Primer Sequences

Name	Sequence 5' → 3'	Application
A1 RV Biotin	(biotin) CTG GGG ACC ATC TGT TCT TGG CCC T	LM-PCR
A2 RV	AAC CTT GAT CTG AAC TTC TC	LM-PCR
A3 RV	CCA TGC CTT GCA AAA TGG C	LM-PCR
OC1 FW	GTA ATA CGA CTC ACT ATA GGG C	LM-PCR

C57BL/6-Tg (Tcr $\alpha$ Tcr $\beta$ ) 1100Mjb/j	OT-1	The Jackson Laboratory, Bar Harbor, Maine, USA

**Table 2-11: Mouse Strains**

### 2.1.13 Tools and Software for Data Analysis

Tool / Software	Provider/Producer
DNASTar Lasergene SeqMan / EditSeq / SeqBuilder	DNASTAR, Inc., Madison, Wisconsin, USA
Expression Console™ Software	Affymetrix, Santa Clara, California, USA
FlowJo	TreeStar Inc, Ashland, Oregon, USA
GraphPad Prism	GraphPad Software Inc., La Jolla, California, USA
Living Image Software 4.0	PerkinElmer, Waltham, Massachusetts, USA
MACSQuantify Software	Miltenyi Biotec, Bergisch Gladbach, Germany
Mavric (Methods for analyzing viral integration clusters)	Departments of Haematology and Bioinformatics, Erasmus MC
PANTHER Classification System	Thomas et al, 2003 (139)
Transcriptome Analysis Console 3.0 Software	Affymetrix, Santa Clara, California, USA

***Table 2-12: Tools and Software for Data Analysis***

## **2.2 Methods**

### **2.2.1 Molecular Biology**

#### **2.2.1.1 DNA digestion**

Digestion of DNA with endonucleases was performed according to the manufacturer's protocol (New England Biolabs, Ipswich, Massachusetts, USA). Unless otherwise stated, reactions were incubated for 1 hour at 37°C in a total volume of 25µl.

#### **2.2.1.2 Agarose gel electrophoresis**

Standard agarose gel electrophoresis was carried out to separate DNA fragments. For preparation of the gel, agarose was dissolved in 1xTAE (Tris-acetate-EDTA) buffer by heating the agarose/buffer mixture in a microwave. Agarose concentration in the gel was typically between 1-2% (w/v). Afterwards, ethidium bromide (EtBr) was added to the mixture at a concentration of 2µg/ml to allow visualization of DNA under UV light exposure. The polymerized gel was then placed into an electrophoresis system with 1xTAE buffer, followed by loading of DNA samples mixed with 6x loading dye. DNA fragments were separated by running the gel at 100-120V for 30-60min, depending on the size of the desired fragments. These fragments were then visualized and documented in a Multi-Imaging System (Fusion-SL, peqLab, Erlangen, Germany).

#### **2.2.1.3 Isolation of DNA fragments from agarose gels**

Single DNA fragments were excised from agarose gels with a clean scalpel. DNA was isolated using a NucleoSpin Gel and PCR Clean-up Kit (Macherey-Nagel, Düren, Germany) by following the manufacturer's instructions.

#### **2.2.1.4 Ligation of DNA-fragments with T4 DNA ligase**

Ligation of insert-DNA into vector-DNA was performed according to the manufacturer's protocol using a molar ratio of 1:3 recipient vector to insert fragment. The reaction volume was increased to 25µl and incubated at 16°C overnight.

### **2.2.1.5 Baterial Transformation**

For amplification, plasmid DNA was transformed into chemically competent *E.coli* TOP10 (Invitrogen). One vial of bacteria (50µl) was thawed and mixed with 100ng of plasmid DNA. The mix was kept on ice for 30min, followed by a short incubation at 42°C for 1min and another 2min on ice. Subsequently, 500µl LB medium was added to the bacteria and incubated at 37°C in a shaking incubator (200rpm) for 45min. Finally, 30-70µl of the bacteria mix were spread on LB plates supplemented with ampicillin and incubated at 37°C overnight. LB plates were examined for colony formation on the following day.

### **2.2.1.6 Preparation of plasmid DNA from bacteria cultures**

After bacterial transformation, single colonies were picked from LB plates with a pipet tip and inoculated in 3ml LB medium supplemented with ampicillin. Bacterial cultures were kept in a shaking incubator (200rpm) at 37°C overnight. For small-scale DNA preparation, DNA was isolated from the overnight cultures using a JETquick Plasmid Miniprep Spin Kit (Genomed, Löhne, Germany) according to the manufacturer's protocol. For large-scale DNA preparation, 200µl from the overnight cultures were added to 200ml LB medium supplemented with ampicillin. The cultures were kept in a shaking incubator (200rpm) at 37°C overnight. DNA was isolated from these cultures using a Qiagen Plasmid Maxi Kit (Qiagen, Hilden, Germany) following the manufacturer's instructions. Finally, DNA concentrations were determined using a NanoDrop (peqLab, Erlangen, Germany).

### **2.2.1.7 DNA isolation from cell suspensions**

For DNA isolation from single cell suspensions,  $1 \times 10^6$  to  $5 \times 10^6$  cells were pelleted and processed using a DNeasy Blood and Tissue Kit (Qiagen, Hilden, Germany) according to the manufacturer's protocol. DNA was eluted with 50µl H<sub>2</sub>O and DNA concentration was determined using a NanoDrop (peqLab, Erlangen, Germany).

### **2.2.1.8 DNA sequencing**

For DNA sequencing at an external sequencing facility (Eurofins Genomics, Ebersberg, Germany), a sequencing reaction mix was prepared using 50-100ng/µl plasmid DNA or 2-10ng/µl purified PCR product in a total volume of 15µl and adding 2µl primer (10µM). This

facility performs Sanger sequencing using an Applied Biosystems 3730xl DNA Analyzer (Life Technologies, Darmstadt, Germany).

### 2.2.1.9 Polymerase chain reaction (PCR)

For DNA amplification, PCR reactions were prepared using a Taq Polymerase (Table 2-13). The reaction tubes were transferred to a thermocycler. The used thermocycler program is shown in Table 2-14. Annealing temperature was adjusted to the melting temperatures of the forward and reverse primer.

Amplification buffer (10x) (Buffer A)	5µl
Forward Primer (10µM)	1µl
Reverse Primer (10µM)	1µl
Taq Polymerase	0.4µl
dNTPs (10mM)	1.5µl
H <sub>2</sub> O	40.1µl
DNA template (50-100ng/µl)	1µl

**Table 2-13: PCR Reaction**

95°C	3min	Initial Denaturation	30 cycles
95°C	30sec	Denaturation	
45-68°C	30sec	Annealing	
72°C	1min	Elongation	
72°C	3min	Final Elongation	

**Table 2-14: Thermocycling Conditions**

### 2.2.1.10 Ligation-mediated PCR (LM-PCR)

Ligation-mediated PCR was performed to determine retroviral integration sites. Therefore, DNA was isolated from single cell suspensions of developed tumors (see section 2.2.1.7). The genomic DNA (250-1000ng) was then digested with the restriction enzyme Tsp5091 (New England Biolabs, Ipswich, Massachusetts, USA) that cuts upstream from the LTR within the proviral sequence. Afterwards, the digestion mix was cleaned up using a MinElute

Reaction Cleanup Kit (Qiagen, Hilden, Germany). Next, the fragments containing LTR-genomic DNA junctions were tagged with a biotinylated LTR-specific primer using a high fidelity DNA polymerase (Finnzymes, New England Biolabs, Ipswich, Massachusetts, USA). The product was cleaned up using a MinElute Reaction Cleanup Kit (Qiagen, Hilden, Germany), followed by incubation with streptavidin-coated beads (Invitrogen, Life Technologies, Darmstadt, Germany) at room temperature for 60min. Afterwards, the mix was washed several times using a magnetic particle concentrator to remove unbound DNA fragments. To be able to specifically amplify the isolated DNA fragments, an adapter oligonucleotide cassette of known sequence was ligated to the fragments using a T4 DNA ligase (New England Biolabs, Ipswich, Massachusetts, USA). After washing the reaction mix, a PCR and a nested PCR (Extensor Hi-Fidelity PCR Master Mix 1, Thermo Fisher Scientific, Waltham, Massachusetts, USA) were performed with oligonucleotides that specifically bind to the adaptor region. PCR products were analyzed by gel electrophoresis (see section 2.2.1.2). Single bands were cut out of the gel and cleaned up (see section 2.2.1.3). The product was then subcloned into a pCR2.1 TOPO vector (Life Technologies, Darmstadt, Germany) following the manufacturer's protocol. Finally, the product was transformed into TOP10 *E.coli* bacteria (see section 2.2.1.5).

#### **2.2.1.11 Colony PCR**

After LM-PCR and transformation of subcloned DNA fragments into bacteria, single colonies were picked and incubated in 50µl PCR reaction mix for 2min. During the following PCR, primers specifically bind to the TOPO plasmid and allow amplification of a single DNA fragment isolated during LM-PCR. Typically, 10 clones were picked per sample. Finally, the PCR reaction was cleaned up using NucleoSpin Gel and PCR Clean-up Kit (Macherey-Nagel, Düren, Germany) and send to an external sequencing facility for DNA sequencing (see section 2.2.1.8).

#### **2.2.1.12 Integration Site Analysis**

During the previously described LM-PCR and colony PCR, retroviral integration sites within the murine genome were isolated and amplified. The resulting DNA sequences contain parts of the proviral LTR on one side and the ligated adapter molecule on the other side. These

sequences were removed from the amplicon using Lasergene's DNASTar SeqMan tool. The remaining sequence was then uploaded to the online tool Mavric (Departments of Haematology and Bioinformatics, Erasmus MC) to analyze the retroviral integration site in terms of exact integration locus, chromosomal location, surrounding genes, distance to surrounding genes and orientation. Thereby, genes 250kb up- and downstream of the integration site were included in this analysis. To further analyze these genes, 'Entrez Gene' IDs were entered into the online PANTHER Gene Ontology database (version 10.0) and characterized in terms of pathways, biological processes and molecular functions. As a reference dataset the 'NCBI build 37 mouse genome' was used.

#### **2.2.1.13 Western Blot**

For protein expression analysis by Western Blot,  $1 \times 10^6$  cells were resuspended in 100 $\mu$ l cell lysis buffer (including protease inhibitors). The mix was kept at 99°C for 10min. Afterwards, samples were loaded onto 4-12% or 12% Bis-Tris Protein Gels (NuPage, Life Technologies, Darmstadt, Germany), depending on protein size. Gel electrophoresis was performed at 40mA for 90min. Subsequently, proteins were eletrophoretically transferred from the polyacrylamide gel onto a polyvinylidene fluoride (PVDF) membrane (Immobilon, Merck Millipore, Billerica, Massachusetts, USA). The membrane was blocked with 1x Roti-Block (Roth, Karlsruhe, Germany) for one hour at room temperature to reduce nonspecific antibody binding. Afterwards, the membrane was incubated with the primary antibody at 4°C overnight. On the following day, the membrane was washed and then incubated with the secondary antibody for 2 hours. For chemiluminescent protein detection, the membrane was treated with the ECL-Plus Western Blot Kit (GE Healthcare Life Sciences, Freiburg, Germany) according to the manufacturer's protocol and analyzed with a Multi-Imaging System (Fusion-SL, peqLab, Erlangen, Germany).

#### **2.2.1.14 Gene Expression Analysis**

For gene expression analysis, RNA was isolated from  $2 \times 10^5$  cells using the RNeasy Mini Kit (Qiagen, Hilden, Germany). After transcription into cDNA, samples were hybridized onto Mouse Gene 1.0 ST Arrays (Affymetrix, Santa Clara, California, USA). Data normalization

and quality control was done using the Affymetrix Expression Console Software. The Affymetrix Transcriptome Analysis Console 3.0 Software was used for data analysis.

## **2.2.2 Cell culture**

### **2.2.2.1 Cell line culture**

The adherent cells lines HEK 293T and SC-1 were cultured in DMEM complete medium (see section 2.1.11). HEK293T cells were passaged when 80% confluent to a ratio of 1:5, typically every 2-3 days. Similarly, SC-1 were subcultured at a 1:10 ratio. Both adherent cell lines were detached from the culture flask by using Trypsin-EDTA. The suspension cell line CTLL-2 was cultured in IMDM CTLL-2 medium (see section 2.1.11). Cultures were maintained at a density of  $1 \times 10^5$  to  $1 \times 10^6$  cells/ml by replacement of medium every 2-3 days. All cell lines were kept in an incubator at 5.9% CO<sub>2</sub> and 37°C.

### **2.2.2.2 Primary single cell suspensions**

Primary cells were isolated from murine spleen, LN, BM, liver and thymus by squeezing the tissue through a 100µm cell strainer with a syringe plunger. Erythrocytes were removed from cell suspensions using 1x lysing buffer (BD, Franklin Lakes, New Jersey, USA). Cells were washed with PBS before further use.

### **2.2.2.3 Primary murine HSC / HPC culture**

Primary hematopoietic stem cells (HSC)/hematopoietic progenitor cells (HPC) were isolated from tibias and femurs of B6 SJL mice (see section 2.2.2.2). After lysis and washing, BM cells were depleted of lineage-committed cells using a Lineage Cell Depletion Kit (Miltenyi Biotec, Bergisch Gladbach, Germany) according to the manufacturer's instructions. Enriched lineage negative cells were resuspended in StemSpan SFEM complete at a density of  $1 \times 10^6$  cells per ml (see section 2.1.11).

#### **2.2.2.4 Primary murine OT-1 T-cell culture**

Primary murine mononuclear cells were isolated from spleen and LNs of OT-1 mice as described before (see section 2.2.2.2). After washing with PBS, cells were resuspended in RPMI mouse special medium (see section 2.1.11) at a density of  $2.5 \times 10^6$  cells per ml. Medium was additionally supplemented with ovalbumin (OVA) peptide (257-264) (10ng/ml) and IL-2 (10U/ml).

#### **2.2.2.5 Flow Cytometry**

Fluorescence activated cell sorting (FACS) was performed to either sort specific cell populations or analyze extra- and intracellular marker expression. Typically,  $1-3 \times 10^7$  cells were used for cell sorting and  $0.5-1 \times 10^6$  cells for flow cytometric analysis. For extracellular staining,  $1 \times 10^6$  cells were resuspended in 100 $\mu$ l PBS with 1 $\mu$ l FcR Blocking Reagent and 0.05-0.5 $\mu$ g antibody. Samples were incubated in the dark for 15min and washed twice with PBS. Cells were analyzed or sorted in PBS with 2% FCS and at a density of  $1 \times 10^7$  per ml. For intracellular staining,  $1 \times 10^6$  cells were treated with the Fix&Perm Cell Permeabilization Kit (Life Technologies, Darmstadt, Germany) following the manufacturer's protocol.

For intracellular staining of phosphorylated protein,  $1-2 \times 10^6$  cells were resuspended in 1x pre-warmed lyse/fix buffer (BD, Franklin Lakes, New Jersey, USA) and incubated at 37°C for 10min. Afterwards cells were washed with stain buffer (500ml PBS, 2,2ml sodium azide, 15ml FCS). Cells were then incubated with Perm Buffer III (BD, Franklin Lakes, New Jersey, USA) on ice for 30min. Subsequently cells were washed twice with stain buffer and then stained with 5 $\mu$ l phospho-antibody. After another 30min of incubation, cells were washed once with stain buffer before analysis.

Antibodies used for FACS staining are shown in Table 2-1. Flow cytometric analysis was performed on a MACSQuant Analyzer (Miltenyi Biotec, Bergisch Gladbach, Germany) and cell sorting on a BD FACSAria II (BD, Franklin Lakes, New Jersey, USA).

#### **2.2.2.6 Retroviral vector production**

For production of replication-defective retroviral vectors, a split packaging approach was followed. Genes encoding for the gene of interest, envelope proteins (Env) and structural and enzymatic proteins (Gag/Pol) were kept on separate plasmids. Only the plasmid encoding the

gene of interest contained the packaging signal  $\Psi$  that allowed packaging into the viral capsid during replication. Consequently, the produced retroviral vectors lacked Env and Gag/Pol genes that are necessary for further replication.

One day before transfection,  $5 \times 10^6$  cells of the packaging cell line HEK293T were seeded in a 10cm tissue culture dish. The following day,  $75 \mu\text{M}$  chloroquine was added to the medium and cells were transfected using a Calcium Phosphate Transfection Kit (Sigma-Aldrich, St.Louis, Missouri, USA). Therefore,  $7.5 \mu\text{g}$  transfer vector,  $12.5 \mu\text{g}$  packaging plasmid (Gag/Pol) and  $1 \mu\text{g}$  envelope (Env) plasmid in  $450 \mu\text{l}$   $\text{H}_2\text{O}$  were mixed with  $50 \mu\text{l}$   $\text{CaCl}_2$  ( $2.5\text{M}$ ) and added dropwise to  $500 \mu\text{l}$   $2 \times$  HEPES buffer while bubbling. The DNA mix was kept at room temperature for 20min and then added to the cells. After 6 hours of incubation the medium was replaced with 5ml DMEM complete medium. Supernatant was collected 24, 36 and 48 hours after transfection, filtered through a  $0.45 \mu\text{m}$  syringe filter and stored at  $4^\circ\text{C}$  (short-term) or  $-20^\circ\text{C}$  (long-term).

#### **2.2.2.7 Retroviral vector titration**

For titration of retroviral supernatants,  $5 \times 10^4$  SC1 cells were seeded in a 24-well tissue culture treated plate. The next day, supernatant was added to the cells using dilutions from 1:1 to 1:100. The culture plate was centrifuged at 2000rpm and  $31^\circ\text{C}$  for 1hour. Transduction efficiencies were determined by flow cytometry 2 days later. The viral titer per ml was calculated as follows: (Percentage of fluorescent cells/100) x number of seeded cells x dilution factor.

#### **2.2.2.8 Retroviral transduction on retronectin-coated plates**

Transduction of cell lines and primary cells was performed on retronectin-coated 6- or 24-well plates. Therefore, 1ml (6-well) or 0.4ml (24-well) retronectin ( $50 \mu\text{g}/\text{ml}$ ) were added to each well and incubated at room temperature for 2 hours or at  $4^\circ\text{C}$  overnight. Afterwards, plates were blocked with 2% BSA in PBS at room temperature for 30min. Plates were washed once with  $1 \times$  HBSS and once with PBS. Subsequently, 1-5ml retroviral supernatant was added to the treated wells and centrifuged at 3100rpm and  $31^\circ\text{C}$  for 90min. Supernatant was removed before adding cells to the wells. For transduction of HSCs/HPCs (see section 2.2.2.3),  $1 \times 10^6$  cells were added to each 24-well the day after cell isolation. These cells were

only transduced once. OVA-stimulated OT-1 T cells (see section 2.2.2.4) were transduced in 3ml medium on a retronectin-coated 6-well plate at a density of  $1.5 \times 10^6$  cells per ml. Transduction was repeated 24 hours after the first transduction. For transduction of the murine cell line CTLL-2, 3ml cell suspension was added to a coated 6-well plate at a density of  $2 \times 10^5$  cells per ml.

## **2.2.3 Animals experiments**

### **2.2.3.1 Animal use**

Laboratory mice were kept in the animal facility of the Georg-Speyer-Haus (Frankfurt am Main) in individually ventilated cages (IVC). All animal use was approved by the regional authority (Regierungspräsidium, Darmstadt, Germany/Tierversuchsnummer: F21/03; FK/1050), and animals were maintained and killed in accordance with the guidelines of the Federation of European Laboratory Animal Science Associations (FELASA).

### **2.2.3.2 Transplantation of HSCs/HPCs**

After isolation (see section 2.2.2.3) and transduction (see section 2.2.2.8) of HSCs/HPCs, cells were analyzed for transduction efficiency and HSC/HPC marker expression (Sca-1, c-Kit) before transplantation into recipient mice. C57BL6 (CD45.2) recipient mice were irradiated with a split dose of 5.5Gy each, with 24 hours between doses, using a BIOBEAM 2000 Cs-137 chloride gamma irradiator (Eckert & Ziegler, Berlin, Germany). One hour after the last dose,  $1 \times 10^6$  cells were transplanted into each recipient mouse.

### **2.2.3.3 Transplantation of OT-1 T cells**

After isolation (see section 2.2.2.4) and two rounds of transduction (see section 2.2.2.8), OT-1 T cells were analyzed for transduction efficiency and lymphocyte marker expression (CD3, CD4, CD8, CD19, V $\alpha$ 2 TCR, V $\beta$ 5 TCR). Afterwards,  $5 \times 10^6$  cells were injected intravenously into each RAG1<sup>-/-</sup> recipient.

#### **2.2.3.4 Blood collection from mice**

Blood samples were taken from recipient mice of transduced HSCs/HPCs or OT-1 T cells to monitor for repopulation and lymphoma/leukemia development. Therefore, the lateral tail vein was gently nicked with a clean scalpel and 25-100µl blood were collected using EDTA-coated microvettes (Sarstedt, Nümbrecht, Germany). Blood samples were prepared for flow cytometric analysis by lysing erythrocytes using 1x lysing buffer (BD, Franklin Lakes, New Jersey, USA).

#### **2.2.3.5 In vivo proliferation assay**

To analyze proliferation of OT-1 T cells upon OVA stimulation in vivo, freshly isolated OT-1 splenocytes (CD45.2) were stained with CellTrace Violet (Life Technologies, Darmstadt, Germany) according to the manufacturer's protocol and  $1 \times 10^6$  cells transplanted into B6 SJL (CD45.1) mice. After transplantation, mice were injected with 25µg OVA/IFA or PBS/IFA (see section 2.2.3.6). Two and five days later mice were sacrificed. Single cell suspensions of the spleen were stained with CD3 and CD45.2 and analyzed by flow cytometry.

#### **2.2.3.6 Stimulation of OT-1 T-cell recipient mice**

For specific OT-1 T-cell stimulation, OT-1 T-cell recipient mice (see section 2.2.3.2) were injected intraperitoneally (i.p.) with 25µg OVA (257-264) in PBS mixed in a 1:1 ratio with incomplete Freund's adjuvant (IFA) every two weeks. Control mice received PBS/IFA (1:1) injections.

#### **2.2.3.7 Necropsy of mice**

Mice were anesthetized with isoflurane prior to euthanasia by cervical dislocation. The thoracic cavity was opened immediately afterwards to allow blood collection via cardiac puncture. The mouse abdomen was opened through midline incisions of the skin and peritoneum. The organs were examined for macroscopic abnormalities. Spleen, liver, lung, LNs (inguinal, axillary, mesenteric), kidney, femur and tibia were isolated for flow cytometric and/or histological analysis.

### **2.2.3.8 Histological analysis**

For histological analysis, organs were fixed in 4% formaldehyde solution overnight. Fixed tissue was then placed into embedding cassettes, dehydrated and finally embedded in paraffin. Paraffin blocks were cut with a microtome into 5-10 $\mu$ m thick sections. Sections were stained with hematoxylin/eosin (HE) and TCLI1A. Sample processing and staining was done in the Senckenberg Institute of Pathology, Frankfurt am Main, Germany. Histological examination was performed by Prof. Dr. Dr. h.c. Martin-Leo Hansmann and Dr. Sylvia Hartmann.

### **2.2.3.9 Bioluminescence Imaging**

*In vivo* imaging was performed for recipient mice of OT-1 T cells transduced with luciferase vectors four weeks after transplantation and repeated every four weeks. Therefore, mice were placed in a XGI-8 anesthesia system (PerkinElmer, Waltham, Massachusetts, USA) flooded with isoflurane gas. Anesthetized mice were shaved and injected i.p. with 150 $\mu$ l D-Luciferin (15mg/ml). Mice were then moved to the IVIS Imaging System Lumina II (PerkinElmer, Waltham, Massachusetts, USA) and imaged 10min after i.p. injection of D-Luciferin. Images were taken in ventro-dorsal and latero-lateral position and acquired after an exposure time of 2 and 5 minutes using binning 4. Signal intensity was quantified as average radiance of photons emitted per second and area (p/s/cm<sup>2</sup>/sr) within a region of interest (ROI) using the Living Image Software 4.0 (PerkinElmer, Waltham, Massachusetts, USA).

### **3. Results**

Syngeneic mouse models using genetically manipulated grafts, offer a valuable method to study and compare cellular transformation *in vivo*. Therefore, a transplantation model established by Newrzela et al using gamma retroviral vectors to introduce oncogenes into HSCs/HPCs and T cells (44) was utilized in this thesis to study oncogenic properties of TCL1 family members (section 3.2.2) and variants (sections 3.2.3-3.2.6) in HSCs/HPCs, and the cooperation of TCL1 and TCR signaling in monoclonal T cells (section 3.3).

#### **3.1 Cloning of retroviral vectors and validation**

For retroviral gene transfer of the different TCL1 family members and variants, gamma-retroviral vectors encoding human TCL1A, TML1, MTCP1, myr-TCL1A and nls-TCL1A were generated (Figure 3-1). Therefore, all cDNAs were cloned in front of the IRES of the previously described gamma retroviral vector MP91-EGFP using the restriction sites EcoRI and NotI (44). The cDNA of human TCL1A and variants were obtained from Michael Teitell, MD (UCLA, USA). The cDNAs of human MTCP1 and human TML1 were purchased from Life Technologies (Darmstadt, Germany) and Source BioScience (Nottingham, UK), respectively. MP91-EGFP was used as a control vector and referred to as “EGFP only” hereafter. For *in vivo* imaging experiments, EGFP was replaced with a firefly luciferase reporter and either T-Sapphire or human TCL1A were cloned in front of the IRES. Luciferase vectors were cloned and provided by Kerstin Cornils, PhD (University of Hamburg). Figure 3-1 shows the design of retroviral vectors used in this thesis.

Successful cloning of retroviral vectors was verified by sequence analysis (data not shown). Additionally, protein expression of our genes of interest was confirmed by Western Blot analysis (Figure 3-2). Comparison of the protein expression level induced by the different TCL1A variants showed that myr-TCL1 was slightly higher expressed than generic TCL1A and nls-TCL1A (Figure 3-2C).

**Figure 3-1: Design of retroviral vectors**

*cDNAs of human TCL1A, myr-TCL1A, nls-TCL1A, MTCP1 and TML1 were cloned into the gamma retroviral vector MP91-EGFP / MP91-Luc. LTR: long terminal repeats. IRES: internal ribosomal entry site. wPRE: Woodchuck hepatitis virus posttranscriptional regulatory element.*

**Figure 3-2: Protein expression of transgenes**

*Western blot analysis of transgene expression in SC-1 cells transduced with MTCP1 (A), TML1 (B), TCL1A and its variants myr-TCL1A and nls-TCL1A (C).*

## 3.2 Targeted expression of TCL1 family members and variants in HSCs/HPCs

### 3.2.1 Transgene expression in mice

To introduce TCL1 family members and variants into HSCs/HPCs, BM cells from C57BL/6 mice (CD45.1) were depleted of lineage-committed cells ( $\text{Lin}^-$  BM cells), transduced and  $1 \times 10^6$  cells were then transplanted into C57BL/6 (CD45.2) recipient mice (Figure 3-3).

#### **Figure 3-3: Experimental design of the HSC/HPC transplantation model**

C57BL/6 (CD45.1) mice were used as donors for  $\text{Lin}^-$  depleted BM cells. These isolated cells were retrovirally transduced and kept in culture for 2 days followed by transplantation into lethally irradiated C57BL/6 (CD45.2) mice. Mice were monitored by blood sampling and analyzed after lymphoma/leukemia development.

Before transplantation into mice, cells were analyzed for transduction efficiency (Figure 3-4A). For all constructs, the HSC/HPC culture showed comparable transduction efficiencies (52-65%). To monitor repopulation of donor HSC/HPC-derived lymphocytes, blood samples were taken from recipient mice six weeks after transplantation and analyzed by flow cytometry. Blood samples were stained with the T-cell marker CD3 and the B-cell marker CD19. Transgene (EGFP) expressing T and B cells were detectable in the PB of recipient mice as shown in Figure 3-4B.

**Figure 3-4: Transduction efficiency and repopulation of HSCs/HPCs**

(A) Percentage of EGFP+ cells within HSC/HPC transplants transduced with TCL1 family members (TCL1A, MTCP1, TML1) and TCL1A variants (myr-TCL1A, nls-TCL1A). (B) Blood samples from HSC/HPC recipient mice were analyzed by flow cytometry for EGFP expressing CD3+ T cells and CD19+ B cells six weeks after transplantation. Error bars represent SD.

### 3.2.2 TCL1A and MTCP1 are oncogenes with similar oncogenic potential

After transplantation of TCL1A, MTCP1, and TML1 transduced HSCs/HPCs, recipient mice developed lymphoid malignancies after latencies between seven and 18 months (Figure 3-5, Table 3-1).

TCL1A HSC/HPC recipient mice developed lymphoma / leukemia after a median latency of 388 days (Figure 3-5). These mice showed an enlarged liver and spleen as well as enlarged mesenteric, inguinal, and/or axillary LNs (Table 3-1, Figure 3-7). All TCL1A mice displayed a leukemic WBC higher than  $15 \times 10^6$  cells per  $\mu$ l peripheral blood (Table 3-1).

**Figure 3-5: Survival of TCL1 family mice**

Animals that received human *TCL1A* (A), *MTCP1* (B) and *TML1* (C) transduced HSCs/HPCs developed lymphoma/leukemia after indicated latencies (black solid line, A-C). Control animals (EGFP only) did not show any signs of disease during the observation time (grey dotted line, A-C).

The phenotype of these tumors was determined by flow cytometric analysis, staining for the basic lymphocyte markers CD3, CD4, CD8, and CD19. Additionally, the leukocyte markers CD45.1 and CD45.2 were analyzed to differentiate between recipient-derived (CD45.2) and donor-derived (CD45.1) cells. All tumor cells isolated from *TCL1A* recipient mice were positive for CD19 and CD45.1. This B-cell phenotype was further characterized using the following markers: CD5, IgM, CD21/35, B220, and CD138 (Table 3-2). The tumor cells did not express the plasma cell marker CD138 and the splenic marginal zone B-cell markers CD21/35. Positive staining was observed for B220 and surface IgM. Tumor cells in most mice expressed CD5 as well (Table 3-2).

Oncogene	Gross-anatomic features	Elevated PB leukocyte count (15x10 <sup>6</sup> cells/ $\mu$ l)	CD4/8 DP	CD19
TCL1A	Hepatomegaly, Splenomegaly, Lymphadenopathy.	5/5	0/5	5/5
MTCP1	Thymoma (CD4/8DP). Hepatomegaly, Splenomegaly, Lymphadenopathy (CD19).	4/4	1/4	3/4
TML1	Thymoma	2/2	2/2	0/2

**Table 3-1: Phenotypes and WBC of tumors induced by TCL1 family genes**  
 DP=double positive.

**Figure 3-6: Flow cytometric analysis of tumors induced by TCL1 family genes**  
 Representative FACS plots of analyzed B-cell tumors (A) and T-cell tumors (B) gated on EGFP positive cells.

MTCP1 HSC/HPC recipient mice developed lymphoma/leukemia after a median latency of 394 days (Figure 3-5). Similar to TCL1A recipient mice, mice developed mostly B-cell malignancies (CD19<sup>+</sup>, B220<sup>+</sup>, IgM<sup>+</sup>, CD5<sup>-</sup>) with elevated WBC and enlarged liver, spleen and LNs (Table 3-1). Only one recipient showed an enlarged thymus with a CD3<sup>+</sup> and CD4/CD8 DP phenotype.

Only two out of 14 TML1 recipient mice developed lymphoma/leukemia, becoming overt at 223 and 371 days after transplantation (Figure 3-5). Therefore, no median survival was reached. The diseased mice displayed enlarged thymi with a CD4/8 DP phenotype, and varying CD3<sup>+</sup> and TCRαβ<sup>+</sup> expression (Table 3-1, Figure 3-6B).

Oncogene	CD19	B220	IgM	CD5	CD138	CD21/35
TCL1A	5/5	5/5	5/5	4/5	0/5	0/5
MTCP1	4/4	4/4	3/4	0/4	0/4	0/4

**Table 3-2: Phenotype of B-cell tumors induced by TCL1 family members**

Sick mice with B-cell malignancies presented with variable hepatomegaly, splenomegaly and lymphadenopathy. Round lymphoblasts with scant cytoplasm were visible in spleen, LN, and liver (Figure 3-7A,B), and were also abundant in blood (Figure 3-8A). Additionally, macroscopic lesions and microscopic infiltrations were often visible in lung and kidney of mice with B-cell malignancies (not shown). Mice with immature T-cell malignancies showed enlarged thymi and mostly no other macroscopic visible abnormalities (Figure 3-7C). Tumor cells had a round lymphoblastoid morphology in thymus (Figure 3-7C) and blood (Figure 3-8B), similar to the one seen in B-cell tumors.

TCL1A-induced tumors were further analyzed for expression of TCL1A by flow cytometry (Figure 3-9A) and by immunohistochemical stainings (Figure 3-9B). All tumors expressed TCL1A and signals were observed in the cytoplasmic and nuclear compartments (Figure 3-9B). A representative plot/image is shown in Figure 3-10.

**Figure 3-7: Gross-anatomic and histological features of B-cell and immature T-cell malignancies induced by TCL1 family genes**

Representative macroscopic images and H&E stained histological sections of animals with B-cell malignancies showing enlarged spleens, LNs (A) (original magnification 20x) and livers (B) (original magnification 10x); and animals with immature T-cell malignancies showing enlarged thymi (C) (original magnification 20x). Scale bar: 20 $\mu$ m.

**Figure 3-9: TCL1A expression in TCL1A-induced tumors**  
 Intracellular TCL1A staining of the blood gated on EGFP+ cells (black line) and EGFP- cells (grey line) (A). Representative immunohistochemical staining for TCL1A of tumor bearing LN (original magnification: 20x, scale bar: 20 $\mu$ m) (B).

### 3.2.3 Targeted expression of TCL1A to the membrane and the nucleus

Engagement of the TCR in T-PLL cells leads to TCL1A recruitment to the cell membrane and later to the nucleus (22). The changing localization of TCL1A during TCR signaling suggests that the protein participates in this process by interacting with different proteins along the signaling cascade. To address the functional impact of TCL1A localization on its oncogenic potential, retroviral vectors containing modified TCL1A transgenes were used to target protein expression to the membrane (myr-TCL1A) or the nucleus (nls-TCL1A).

**Figure 3-10: TCL1A protein localization in HEK293T cells after transduction with different TCL1A variants**

Fluorescence microscopy on TCL1A (second row), myr-TCL1A (third row) and nls-TCL1A (fourth row) transduced HEK293T cells. Non-transduced HEK293T cells were used as a negative control (first row). Staining was done using DAPI (blue, left column) and anti-TCL1A (green, middle column). Merged pictures are shown in the right column.

For membrane localization, a DNA sequence for an N-terminal myristoylation signal was added to the transgene sequence. This signal allows cotranslational modification resulting in the attachment of a myristic acid to the N-terminus of TCL1A (myr-TCL1A). Myristic acid is hydrophobic and anchors the protein into the lipid bilayer of the cell's membrane. For nuclear localization, a DNA sequence for an N-terminal nuclear localization signal (nls) was added to the transgene sequence. This peptide motif tags the protein for traffic through nuclear pores into the nucleus. To validate targeted TCL1A expression, HEK293T cells were transduced with retroviral vectors for TCL1A, myr-TCL1A and nls-TCL1A, and analyzed by fluorescence microscopy for TCL1A expression (Figure 3-10). For this analysis, HEK293T cells were chosen as their larger size allowed studying protein distribution in cellular compartments. HEK293T cells expressing the generic TCL1A showed an even distribution of the protein in the cytoplasm and nucleus (Figure 3-10, second row). Myr-TCL1A expressing cells showed condensed protein localization at the membrane (Figure 3-10, third row). A nuclear accumulation of TCL1A was observed for nls-TCL1A transduced HEK293T cells (Figure 3-10, fourth row). Therefore, targeted expression of TCL1A to the membrane and nucleus with myr-TCL1A and nls-TCL1A was validated.

#### **3.2.4 Localization of TCL1A influences its oncogenic potential**

Transplantation of myr-TCL1A and nls-TCL1A transduced HSCs/HPCs resulted in lymphoma/leukemia development in recipient mice after latencies between five and 20 months. Survival was compared to the previously described cohort of generic TCL1A recipient mice (see section 3.2.2). TCL1A HSC/HPC recipient mice developed lymphoma/leukemia after a median latency of 388 days. Similarly, myr-TCL1A recipient mice had a median survival of 372 days (Figure 3-11A). However, survival was significantly reduced in nls-TCL1A recipients compared to recipient mice of TCL1A HSCs/HPCs with a median latency of 349 days (Figure 3-11B). Despite a reduced latency in nls-TCL1A mice, no striking difference in phenotype was observed between tumors induced by the generic TCL1A and its variants. Similar to TCL1A-induced tumors, most myr-TCL1A and nls-TCL1A mice developed tumors with a B-cell phenotype and presented with enlarged liver, spleen and LNs (Table 3-3). The remaining mice, showed enlarged thymi with a DP or DN T-cell phenotype (Table 3-3). An elevated WBC ( $>15 \times 10^6$  cells/ $\mu$ l blood) was detected in the majority of myr-TCL1A and nls-TCL1A recipient mice upon tumor development (Table 3-3).

Flow cytometric analysis of B-cell tumors induced by myr-TCL1A and nls-TCL1A showed expression of CD19, surface IgM, and B220, except for one nls-TCL1A tumor that lacked surface IgM expression (Table 3-4). None of the B-cell tumors expressed CD138 or CD21/35 (Table 3-4). CD5 expression was only detected in half of the tumors induced by myr-TCL1A tumors and nls-TCL1A, whereas most tumors derived from overexpression of generic TCL1A expressed this marker (Table 3-4). A representative flow cytometric analysis is shown in Figure 3-6A.

**Figure 3-11: Survival of TCL1A variants mice**

Animals that received TCL1A variants myr-TCL1A (A) and nls-TCL1A (B) transduced HSCs/HPCs developed lymphoma/leukemia after indicated latencies (blue solid line, A-B). Survival of the previously described recipient mice of generic TCL1A is shown as black solid line in each graph. Control animals (EGFP only) did not show any signs of disease during the observation time (grey dotted line, A-B).

Myr-TCL1A and nls-TCL1A HSC/HPC recipient mice that developed T-cell malignancies displayed enlarged thymi with a CD4/8 DP phenotype and varying expression of CD3 and TCR $\alpha\beta$ . A representative flow-cytometric analyses is shown in Figure 3-6B. Only one T-cell tumor induced by myr-TCL1A was negative for CD4 and CD8 expression (CD4/8 DN) (Table 3-3), but showed TCR $\alpha\beta^+$  expression (data not shown).

Representative images of macroscopic and histological/cytological analyses of B- and T-cell malignancies are shown in Figure 3-7 and Figure 3-8, as they had the same cytomorphologic features as tumors induced by non-compartment targeted TCL1A overexpression.

Oncogene	Gross-anatomic features	Elevated PB leukocyte count (15x10 <sup>6</sup> cells/ $\mu$ l)	CD4/8 DP	CD4/8 DN	CD19
TCL1A	Hepatomegaly, Splenomegaly, Lymphadenopathy.	5/5	0/5	0/5	5/5
myr-TCL1A	Thymoma (CD4/8DP). Hepatomegaly, Splenomegaly, Lymphadenopathy (CD19).	13/16	3/16	1/16	12/16
nls-TCL1A	Thymoma (CD4/8DP). Hepatomegaly, Splenomegaly, Lymphadenopathy (CD19).	12/15	2/15	0/15	13/15

*Table 3-3: Phenotype of tumors induced by TCL1A variants*

*Table 3-4: Phenotype of B-cell tumors induced by TCL1A variants*

### 3.2.5 The primary oncogenic function of TCL1A depends on its nuclear presence

A comparative gene expression analysis of the TCL1A variants was performed to identify differently expressed genes in target cells at overt leukemic phases. These analyses were performed on an Affymetrix Mouse Gene 1.0 ST Array, whose 764885 probes cover a total of murine 28869 genes. Differently expressed genes were filtered using a fold-change of 2 (up and down) and an ANOVA p-value lower than 0.05.

For tumor cell analysis, cell suspensions from spleens of mice with B-cell malignancies were used with at least 70% tumor cell content. Gene expression profiles of tumor samples from TCL1A, myr-TCL1A and nls-TCL1A recipient mice were compared to CD19<sup>+</sup>EGFP<sup>+</sup> B cells sorted from spleen and LNs of EGFP only control mice 100 days after transplantation (Figure 3-12).

**Figure 3-12: Differently expressed genes in TCL1A-, myr-TCL1A- and nls-TCL1A-induced tumors compared to control B cells**

Volcano plots of up-regulated (red) and down-regulated (green) genes with a fold change (FCh) of 2. Genes in grey did not match the filter criteria (FCh>2, P<0.05) and were excluded from further analysis.

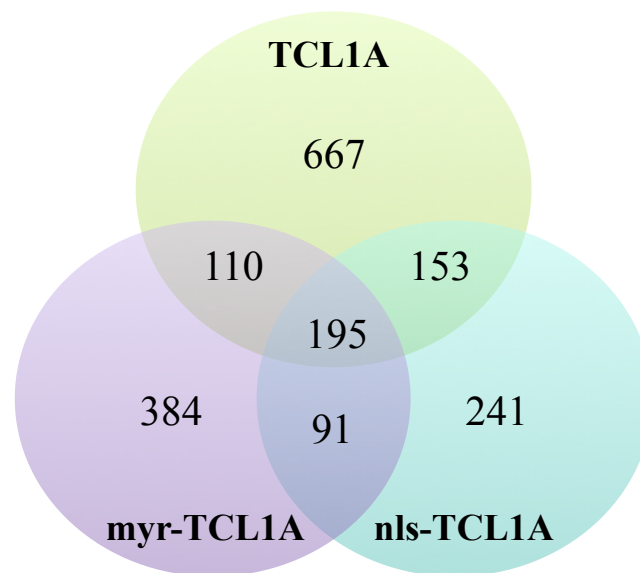

A pathway enrichment analysis was performed to characterize the functional role of differently expressed genes. There was a large overlap within the ten most affected pathways in TCL1A-, myr-TCL1A-, and nls-TCL1A-induced tumors including chemokine, cell cycle, PI3K/AKT, p53, and MAPK signaling pathways (Figure 3-13). Interestingly, a lot of receptor-induced signaling pathways were deregulated in these tumors involving the BCR, cytokine receptors, chemokine, and other G protein-coupled receptors (GPCRs). A list of genes that are up-regulated or down-regulated in at least two of three cohorts are shown in Table 5-1 in the supplementary section 5.3.

**Figure 3-13: Top 10 pathways affected in TCL1A-, myr-TCL1A- and nls-TCL1A-induced tumors compared to control B cells**

Pathway enrichment analysis of differently expressed genes in TCL1A- (A), myr-TCL1A- (B), and nls-TCL1A-induced (C) tumors compared to control B cells.

Next, the relation of compartment-targeting variants of TCL1A to unmodified TCL1A was characterized. The numbers of overlapping genes that are differently expressed in the three TCL1A cohorts are shown in Figure 3-14. The largest overlap was observed between the generic TCL1A and its nuclear variant nls-TCL1A.

**Figure 3-14: Overlap of differently expressed genes in *TCL1A*-, *myr-TCL1A*- and *nls-TCL1A*-induced tumors**

*Venn diagram showing the number of differently expressed genes in B-cell tumors induced by *TCL1A*, *myr-TCL1A* and *nls-TCL1A*.*

This overlap was further supported by a pathway enrichment analysis of deregulated genes in TCL1A-induced tumors compared to tumors induced by myr-TCL1A and nls-TCL1A (Figure 3-15). There was no significant enrichment within the top ten pathways between tumors of TCL1A and nls-TCL1A recipient mice.

Noteworthy is also the more than 2-fold down-regulation of the TCL1 family gene *Mtcp1* in TCL1A-induced tumors (data not shown). Expression of the murine TML1 isoforms was not affected.

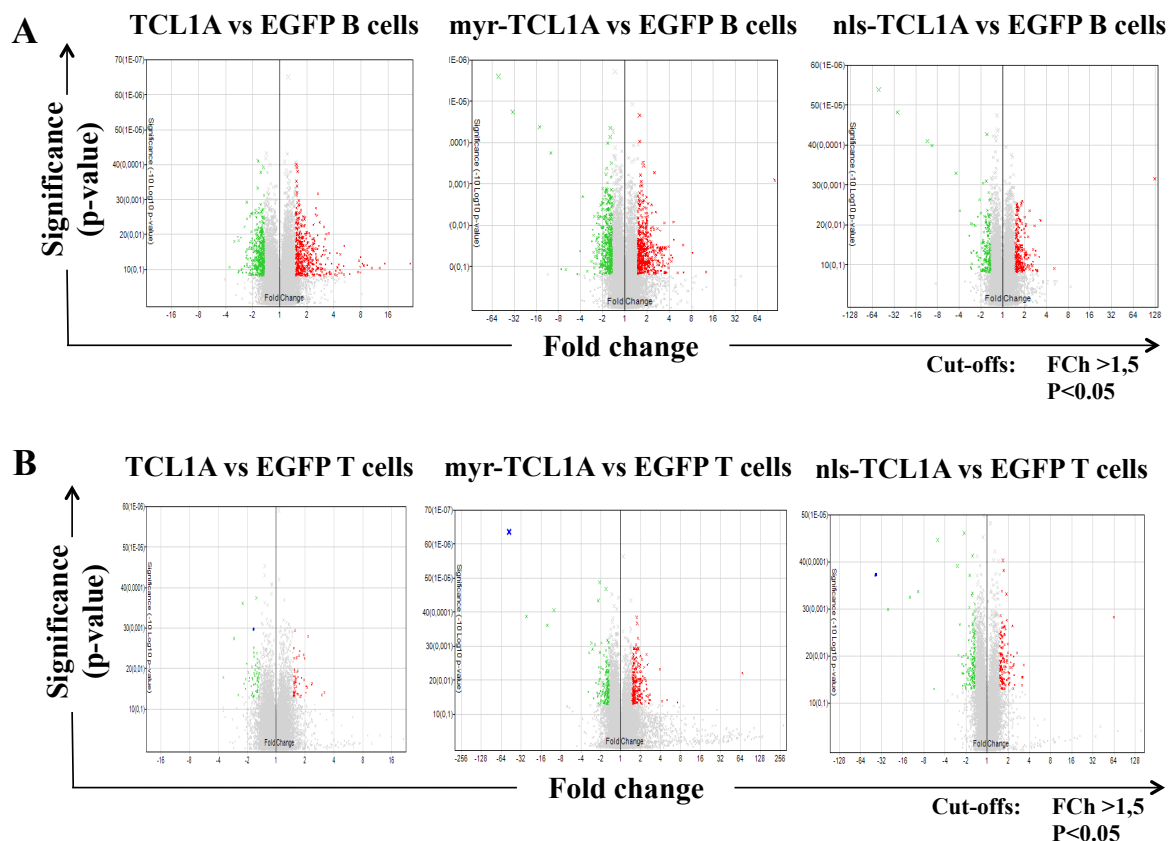

**Figure 3-15: Top 10 pathways affected in tumors induced by TCL1A compared to tumors induced by compartment-targeting TCL1A variants**

Pathway enrichment analysis of differently expressed genes in TCL1A-induced tumors compared to myr-TCL1A-induced tumors (A) and nls-TCL1A-induced tumors (B).

### 3.2.6 TCL1A-induced changes in gene expression are more prominent in B cells than in T cells at pre-leukemic stages

To characterize TCL1A-induced changes in gene expression of lymphocytes at pre-leukemic phases, CD19<sup>+</sup> EGFP<sup>+</sup> B and CD3<sup>+</sup> EGFP<sup>+</sup> T cells were sorted from spleen and LNs of EGFP only, TCL1A, myr-TCL1A and nls-TCL1A HSC/HPC mice 100 days after transplantation. This time point was chosen based on tumor latencies that showed that the earliest tumor arose 131 days after transplantation (Figure 3-11). Analyses were performed on the previously described Affymetrix Mouse Gene 1.0 ST Array. Due to the low number of differently expressed genes in T cells, results were filtered using a fold-change of 1.5 (up and down) and

an ANOVA p-value lower than 0.05. Gene expression in sorted B and T cells from TCL1A, myr-TCL1A and nls-TCL1A recipient mice, was compared to sorted B and T cells from EGFP only control mice (Figure 3-16). Interestingly, a significant higher number of genes were differently expressed in B cells (more than 400 genes per cohort) than in T cells (less than 400 genes per cohort) at the pre-leukemic phase (Figure 3-16).

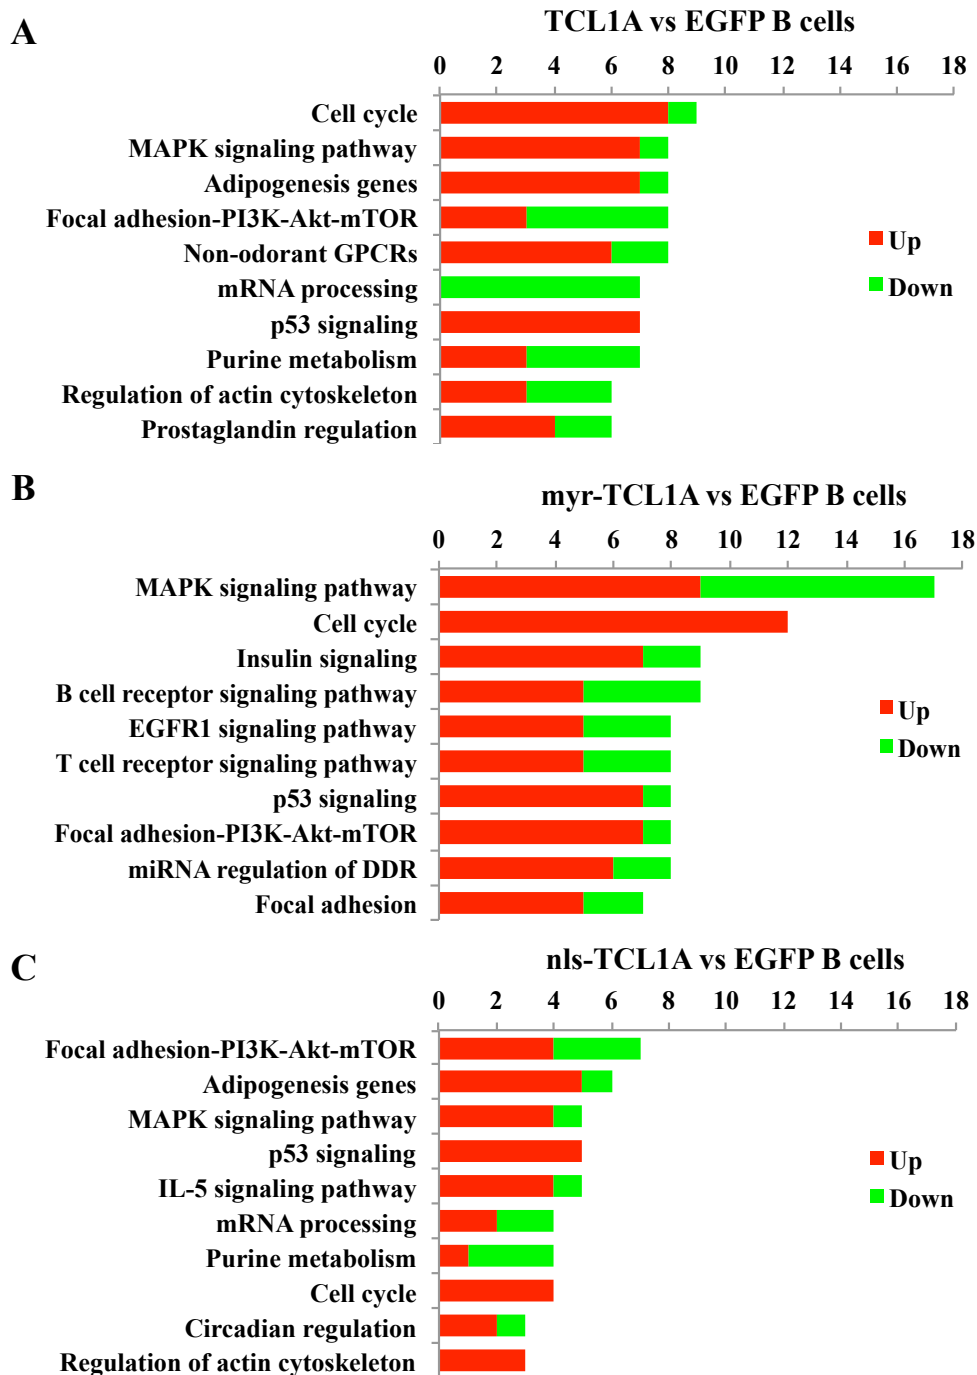

**Figure 3-16: Differently expressed genes in TCL1A, myr-TCL1A and nls-TCL1A expressing B and T cells compared to control cells**

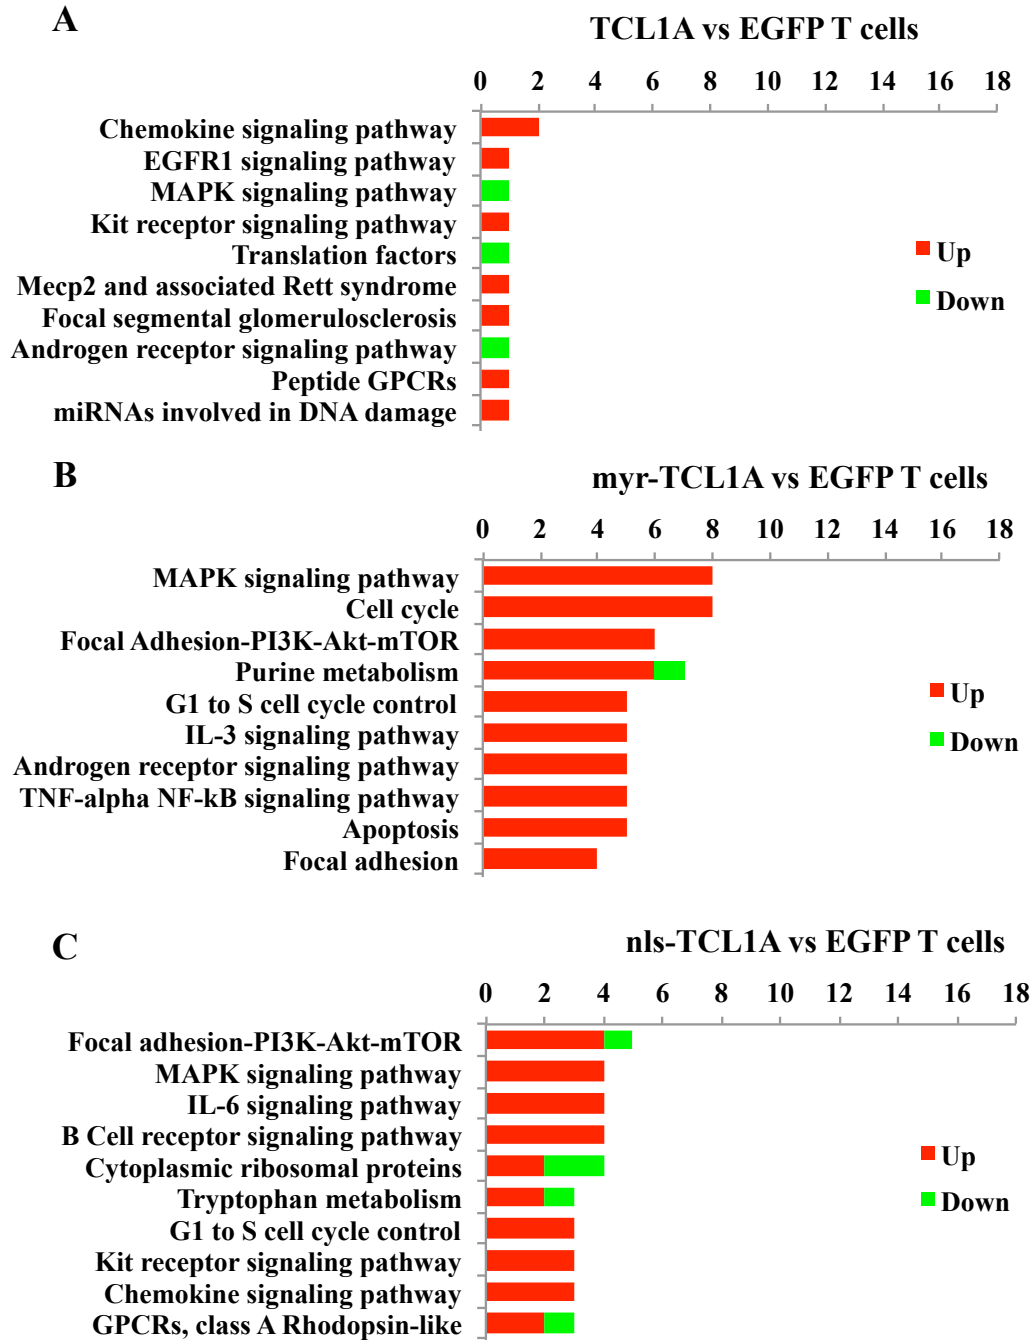

Volcano plots of up-regulated (red) and down-regulated (green) genes with a fold change (FCh) of 1.5. Genes in grey did not match the filter criteria (FCh > 1.5, P < 0.05) and were excluded from further analysis.

To further classify the functional role of differently expressed genes, a pathway enrichment analysis was performed. Genes involved in chemokine, PI3K/AKT, and MAPK signaling pathways were differently expressed in pre-leukemic B and T cells (Figure 3-17, Figure 3-18). Additionally, pre-leukemic B cells showed a deregulation of genes involved in cell cycle and p53 signaling. A list of genes that are up-regulated or down-regulated in pre-leukemic B and

T cells from at least two of three cohorts are shown in Table 5-2 and Table 5-3 in the supplementary section 5.3.

**Figure 3-17: Top 10 pathways affected in *TCL1A*, *myr-TCL1A* and *nls-TCL1A* pre-leukemic B cells compared to control B cells**  
 Pathway Enrichment Analysis of differently expressed genes in *TCL1A* (A), *myr-TCL1A* (B) and *nls-TCL1A* (C) B cells 100 days after transplantation compared to control B cells.

**Figure 3-18: Top 10 pathways affected in TCL1A, myr-TCL1A and nls-TCL1A pre-leukemic T cells compared to control T cells**

Pathway Enrichment Analysis of differently expressed genes in TCL1A (A), myr-TCL1A (B) and nls-TCL1A (C) T cells 100 days after transplantation compared to control T cells.

The numbers of overlapping genes that are differently expressed in pre-leukemic B and T cells of the three TCL1A cohorts are shown in Figure 3-19 to study the relation of different TCL1A variants. In pre-leukemic B cells, the biggest overlap was observed between B cells expressing the generic TCL1A and B cells expressing myr-TCL1A (Figure 3-19A). In T cells, the biggest overlap was found in T cells expressing myr-TCL1A and T cells expressing nls-TCL1A (Figure 3-19B).

Similar to the gene expression in TCL1A B cells at the tumor stage, day 100 B cells showed a 1.5-fold down-regulation of a TCL1 family member, in this case Tcl1b4 (data not shown).

**Figure 3-19: Overlap of differently expressed genes in TCL1A, myr-TCL1A and nls-TCL1A B and T cells**

Venn diagrams showing the number of differently expressed genes in pre-leukemic B cells (A) and T cells (B) of TCL1A, myr-TCL1A and nls-TCL1A HSC/HPC recipient mice.

### 3.3 Targeted expression of TCL1A variants in monoclonal T cells

#### 3.3.1 Specific TCR stimulation in vivo

For the second aim of this thesis, the chimeric model was modified using transplanted T cells as target cells instead of reconstitution by HSCs/HPCs. Single cell suspensions from spleens and LNs of OT-1 transgenic TCR mice were retrovirally transduced with TCL1A and its variants myr-TCL1A and nls-TCL1A. Subsequently,  $5 \times 10^6$  transduced cells were transplanted into RAG1<sup>-/-</sup> recipient mice (no irradiation) that lack mature T and B cells (Figure 3-20). CD8 T cells from OT-1 mice exclusively express a monoclonal TCR that specifically recognizes the OVA peptide (amino acids 257-264) and is composed of a Valpha2 (V $\alpha$ 2) and a Vbeta5 (V $\beta$ 5) chain. Therefore, the TCR of transgenic OT-1 T cells can be stimulated specifically, which allows to study the impact of chronic TCR engagement on TCL1A-driven transformation. In the presented model, TCR stimulation was initiated by injecting recipient mice i.p. with OVA (257-264) in PBS mixed with the adjuvant IFA every two weeks. This mix was prepared to generate water-in-oil emulsions that serve as antigen depots at the injections site. Control mice were injected with a PBS/IFA mix. Control mice were injected with a PBS/IFA mix.

**Figure 3-20: Experimental design of the T-cell transplantation model**

TCR transgenic (tg) OT-1 mice were used as donors for mature T cells. These cells were retrovirally transduced and kept in culture for 3 days followed by transplantation into RAG1<sup>-/-</sup> recipient mice. Every two weeks, mice were injected with an OVA/IFA or PBS/IFA mix. Mice were monitored by blood sampling and analyzed after lymphoma/leukemia development.

Before using OVA/IFA injections in the described transplantation model, the responsiveness of OT-1 T cells to OVA stimulation was first analyzed *in vivo*. For that, OT-1 splenocytes (CD45.2) were stained with the proliferation marker CellTrace Violet and transplanted into B6 SJL WT (CD45.1) mice. WT mice were used as recipients for this experiment instead of RAG1<sup>-/-</sup> mice, as T cells undergo spontaneous proliferation in lymphopenic mice without the presence of a TCR stimulus, thereby not allowing to study the effect induced by the injection of OVA. After transplantation, mice were injected with OVA/IFA or PBS/IFA. Spleen suspensions were analyzed two and five days after transplantation for proliferation within the donor cell population (CD45.2<sup>+</sup>, CD3<sup>+</sup>) (Figure 3-21). Donor splenocytes in OVA/IFA-injected mice showed distinct inductions of proliferation after two days, whereas donor splenocytes in PBS/IFA-injected mice did not show any proliferative activity at this time point (Figure 3-21, left panel). After five days, the CellTrace Violet fluorescent signal had mostly disappeared within the high proliferating donor cell population of OVA stimulated mice, but was still detectable in slow proliferating donor cells of PBS control mice (Figure 3-21, right panel). OT-1 T cells responded to OVA/IFA injections and were thus applicable for chronic TCR engagement in the T-cell transplantation model.

**Figure 3-21: Proliferation of OT-1 T cells *in vivo***

B6 SJL WT mice were injected with PBS/IFA (w/o stim) or PBS/OVA (OVA stim) after transplantation of CellTrace Violet stained OT-1 splenocytes. Mice were sacrificed two and five days later. Spleen suspensions were analyzed by flow cytometry for CellTrace labeled generations of proliferating, donor derived (CD45.2, CD3) OT-1 T cells.

Next, the transplantation model as shown in Figure 3-20 was set up. Phenotype and transduction efficiency of OT-1 T-cell cultures were analyzed by flow cytometry before transplantation into recipient mice (Figure 3-22A). All retrovirally transferred constructs showed comparable transduction efficiencies (35-50%). Phenotypically, transgenic CD8<sup>+</sup> Va2/Vβ5 DP T cells made up >95% of the cells in this culture. The remaining cells were comprised of CD19<sup>+</sup> B cells (<4%) and CD4<sup>+</sup> T cells (<1%).

**Figure 3-22: Transduction efficiency and repopulation of OT-1 T cells**  
 (A) Percentage of EGFP<sup>+</sup> T cells transduced with TCL1A variants (TCL1A, myr-TCL1A, nls-TCL1A).  
 (B) Blood samples from OT-1 T cells recipient mice were analyzed by flow cytometry for EGFP expressing T cell populations (CD3<sup>+</sup>, CD4<sup>+</sup>, CD8<sup>+</sup> and Va2/Vβ5 DP) and CD19<sup>+</sup> B cells two weeks after transplantation. Error bars represent SD.

To monitor repopulation of OT-1 T cells, blood samples were drawn from recipient mice two weeks after transplantation and analyzed by flow cytometry. Blood samples were stained with the B-cell marker CD19, transgenic TCR markers Va2 and Vβ5, as well as the T-cell markers CD3, CD4, and CD8. CD8 and Va2/Vβ5 DP T cells accounted for around 98% of the transgenic (EGFP<sup>+</sup>) lymphocytes in PB (Figure 3-22B). CD19<sup>+</sup> B cells and CD4<sup>+</sup> T cells made up less than 2% of the EGFP<sup>+</sup> population. Blood analysis was repeated every four weeks until mice developed lymphoma/leukemia (Figure 3-23).

**Figure 3-23: Monitoring of transduced OT-1 T cells in the PB over time**

Blood samples were taken from unstimulated (green, w/o stim) and stimulated (red, OVA stim) EGFP only (circle) and TCL1A (triangle) OT-1 T-cell recipient mice every four weeks and analyzed by flow cytometry. Mean percentage of CD3<sup>+</sup> cells gated on live cells (top left), EGFP<sup>+</sup> cells gated on CD3<sup>+</sup> cells (top right), CD8<sup>+</sup> (middle left), CD4<sup>+</sup> (middle right) and CD4/8 DP (bottom left) cells gated on CD3<sup>+</sup> and EGFP<sup>+</sup> cells was compared between different cohorts throughout the whole observation time. Experiment was started with five mice per group. Symbols represent mean values and error bars represent SD.

In OVA stimulated EGFP and TCL1A cohorts, the percentage of CD3<sup>+</sup> T cells dropped within the first 12 weeks after the first injection (Figure 3-23). Interestingly, stimulated TCL1A mice showed an increase of CD3 percentage after the initial decline, whereas in stimulated EGFP only mice this percentage remained low until the end of the experiment. The percentage of transgene/EGFP expressing cells within the CD3<sup>+</sup> population of these two cohorts rose almost to up to 100% in TCL1A recipients and to 80% in EGFP control mice. Surprisingly, unstimulated TCL1A showed a comparable increase in EGFP percentage as OVA stimulated EGFP mice. Although the initial transplant mainly consisted out of transgenic CD8 T cells, TCL1A cohorts also showed a significant decline of EGFP<sup>+</sup> CD8 T cells and an increase of EGFP<sup>+</sup> CD4 T cells instead (Figure 3-23). The percentage of CD19<sup>+</sup> B cells in the PB was less than 5% throughout the entire observation time in all cohorts (data not shown). The blood analysis of TCL1A mice shown in Figure 3-23 is representative for its two variants myr-TCL1A and nls-TCL1A, as these groups show similar expression patterns in the PB during the experiment.

To characterize the functional phenotype of OT-1 T cells in recipient mice, blood samples were further analyzed for the T-cell markers CD69, CCR7, CD62L and CD44 (see section 1.1.2). Most TCL1A transduced T cells in OVA stimulated recipient mice showed a typical T<sub>EM</sub> profile as they expressed CD44, but lacked expression of CD69, CCR7, and CD62L (Figure 3-24). Only small subpopulations showed expression of CCR7, CD62L and CD69. Stimulated EGFP only transduced T cells showed the same expression pattern with the exception to CD62L, which was detected on almost half of the cells (Figure 3-24). The T cells of unstimulated EGFP only and TCL1A cohorts showed mostly a high expression of CD62L and CD44, while only a small population expressed CCR7 and CD69 expression was completely absent. Again, myr-TCL1A and nls-TCL1A expressing T cells showed a similar functional phenotype as TCL1A<sup>+</sup> T cells shown in Figure 3-24.

**Figure 3-24: Functional phenotype of transduced OT-1 T cells in the PB**

Flow cytometric analysis of EGFP<sup>+</sup> cells in the PB of PBS/IFA (w/o stim) and OVA/IFA (OVA stim) injected OT-1 T-cell recipient mice 36 weeks after transplantation. Cells were gated on EGFP<sup>+</sup> cells and analyzed for the expression of CCR7 and CD62L (left panel), and CD69 and CD44 (right panel) in EGFP only (top row) and TCL1A (bottom row) cohorts. FACS plots show mean percentage and SD of sub-gates of five analyzed animals.

### 3.3.2 Stimulated TCL1A T cells accumulate in spleen and other abdominal regions

Analysis of the PB showed that the percentage of CD3<sup>+</sup> cells decreased upon TCR stimulation with OVA. Without sacrificing the mice, it was not possible to determine the localization of the transplanted T cells in other organs. Thus, a retroviral vector with a luciferase reporter was utilized to visualize T-cell localization by in vivo imaging (Figure 3-1). The control vector contained a T-Sapphire reporter gene in addition to the luciferase reporter. The control vector and TCL1A vector were both transduced into OT-1 T cells with a comparable transduction efficiency of around 20% (data not shown). Twelve weeks after the first PBS or OVA injection, mice were analyzed by bioluminescence imaging (Figure 3-25). This analysis was done 10 days after the last injection.

**Figure 3-25: Bioluminescence imaging of OT-1 T-cell mice**

Bioluminescence imaging of unstimulated (w/o stim) and stimulated (OVA stim) control and TCL1A OT-1 T-cell recipient mice. (A) For all images shown, the color scale for bioluminescence displayed as average radiance ranges from  $5 \times 10^4$  (blue) to  $1 \times 10^6$  (red) photons/s/cm<sup>2</sup>/sr. (B) For each group of mice, whole body bioluminescence signals were determined and shown as mean values of average radiance relative to the unstimulated control group. Error bars represent RSD.

The strongest whole body bioluminescence signals, expressed as average radiance, were detected in OVA stimulated mice (Figure 3-25). Relative to unstimulated control mice, this signal was approximately 60 times higher for stimulated TCL1A mice, 10 times higher for stimulated control mice, and 5 times higher for unstimulated TCL1A mice (Figure 3-25B). To narrow down the localization of transplanted cells, signals were determined for selected regions of interest (ROI) (Figure 3-26A). Average radiance for each ROI relative to the cervical LN of each cohort is shown in Figure 3-26B. In unstimulated control and TCL1A mice, the strongest signal was found in the abdominal regions and the spleen (Figure 3-26B). Based on the strong signal in the abdominal regions, it was not possible to narrow down the exact tissues involved; and an intestinal origin is a rather speculated site. Cervical, axillary, and inguinal LN showed an evenly distributed signal in these mice. In OVA stimulated cohorts, the signal was low in cervical and axillary LNs, but high in regions of the inguinal LNs, abdominal regions, and spleen (Figure 3-26B).

**Figure 3-26: Bioluminescence signals in selected regions of interest**

Bioluminescence imaging of unstimulated (w/o stim) and stimulated (OVA stim) control and TCL1A OT-1 T-cell recipient mice. (A) In ventro-dorsal position of the mouse, regions of interest (ROI) were drawn for the abdominal regions and cervical, axillary and inguinal LNs (left). In latero-lateral position, a ROI was drawn for the spleen (right). (B) For each group of mice, bioluminescence signals were determined for each ROI and shown as mean values of average radiance relative to its own cervical LN ROI. Error bars represent RSD.

### 3.3.3 Constant TCR stimulation facilitates TCL1A-driven transformation

After transplantation of TCL1A, myr-TCL1A and nls-TCL1A transduced OT-1 T cells, PBS/IFA injected recipients developed lymphoid malignancies after latencies between 7 and 20 months, whereas mice receiving OVA/IFA injections showed a significantly reduced survival between 6.5 and 13.5 months (Figure 3-27).

**Figure 3-27: Survival of OT-1 T-cell recipient mice**

Recipient mice of TCL1A (A), myr-TCL1A (B) and nls-TCL1A (C) transduced OT-1 T cells were injected with IFA/PBS (w/o stim, red dotted line) or IFA/OVA (OVA stim, red solid line) every two weeks and developed lymphoma/leukemia after significant different latencies. Control animals (EGFP only) that were treated with IFA/PBS (w/o stim, green dotted line) or IFA/OVA (OVA stim, green solid line) did not show any signs of disease during the observation time (A-C).

Recipient mice of TCL1A transduced OT-1 T cells that were injected with PBS had a median survival of 417 days. Repeated stimulation of the OT-1 TCR through OVA injections, led to a significant reduction of the median survival to 305 days (Figure 3-27). The same was observed for stimulated and unstimulated recipient mice of myr-TCL1A and nls-TCL1A

variants. All groups presented with splenomegaly, variable enlargement of mesenteric, inguinal and/or axillary LNs, as well as leukemic WBC higher than  $15 \times 10^6$  cells per  $\mu\text{l}$  blood (Table 3-5). The phenotype of these tumors was determined by flow cytometric analysis, staining for CD3, CD4, CD8, and CD19 (Table 3-5). Recipient mice of OT-1 T cells transduced with TCL1A variants developed mostly T-cell malignancies. Interestingly, a few mice of the unstimulated cohorts developed B-cell tumors.

Oncogene		Gross-anatomic features	Elevated PB leukocyte count ( $15 \times 10^6$ cells/ $\mu\text{l}$ )	CD4/8 DP	CD4 SP	CD8 SP	CD19
TCL1A	+	Splenomegaly, Lymphadenopathy	7/7	0/7	3/7	4/7	0/7
	-	Splenomegaly, Lymphadenopathy	6/6	1/6	3/6	0/6	2/6
myr-TCL1A	+	Splenomegaly, Lymphadenopathy	3/5	0/5	4/5	1/5	0/5
	-	Splenomegaly, Lymphadenopathy	3/9	1/9	4/9	2/9	2/9
nls-TCL1A	+	Splenomegaly, Lymphadenopathy	2/3	0/3	3/3	0/3	0/3
	-	Splenomegaly, Lymphadenopathy	5/6	1/6	3/6	0/6	2/6

**Table 3-5: Phenotype of tumors induced by TCL1A variants in OT-1 transplantation model**  
 + = OVA stimulation, - = w/o stimulation

**Figure 3-28: Histological and cytomorphological features of T- and B-cell malignancies induced by TCL1 family genes in OT-1 transplantation model**

Representative H&E stained histological sections of animals with T-cell (A) and B-cell (B) malignancies showing enlarged spleens and LNs (original magnification 20x), infiltrations in the liver (original magnification 10x) and PB. Scale bar: 20 $\mu$ m.

Clinically apparent mice with T- and B-cell malignancies presented with variable splenomegaly and lymphadenopathy. Cytological analysis showed medium-sized lymphoid cells with scant basophilic cytoplasm in the blood of mice that developed tumors with a T-cell phenotype (Figure 3-28A). These tumor cells also infiltrated the spleen, LNs, and liver (Figure 3-28A). B-cell tumors in this model showed round medium-sized lymphoid cells with a high nucleo-cytoplasmic ratio in the blood that appeared more mature than the ones seen in the HSC/HPC model (Figure 3-28B). These cells were also found in spleen, LNs, and liver (Figure 3-28B). Infiltrations in lung and kidney were often observed for both T- and B-cell tumor types (data not shown)

LM-PCR analyses were performed using genomic DNA from tumor tissue to determine clonality of the T-cell tumors and to identify integration sites of retroviral vectors within the host cell genome. Tumors were classified based on the number of identified clones into monoclonal, oligoclonal, and polyclonal tumors. Figure 3-29 shows a typical pattern of monoclonal (1 band), oligoclonal (more than 1 band), and polyclonal samples (smear). The internal control for gammaretroviral vectors is visible as a 200bp band. Tumors of all cohorts showed a monoclonal or oligoclonal pattern, summarized in Table 3-6.

**Figure 3-29: LM-PCR Analysis of tumors**

*Representative gel image for monoclonal (Lane 1 and 2), oligoclonal (Lane 3) and polyclonal (Lane 4, “smear”) band patterns. Tissue from EGFP control mice was used as an example for a polyclonal pattern. The 200bp band represents internal control (←).*

Retroviral integration sites were further analyzed based on the genes that are found within a 250kb distance up- and downstream of the integration site. Affected genes in tumors of unstimulated mice (Table 3-7) and OVA stimulated mice (Table 3-8) were functionally characterized using the PANTHER pathway classification system. Generally, there was no statistical overrepresentation of flanking genes involved in signaling pathways. However, similar signaling pathways were affected in the different tumor cohorts, e.g. CCKR signaling,

inflammation mediated by chemokine and cytokine signaling pathway, PI3 Kinase pathway, etc. A complete list of identified genes can be found in section 5.4.

### 3.3.4 TCL1A functions as a signaling enhancer in vitro

In vitro studies with OT-1 T cells are challenging, as these primary cells do not survive long enough in culture to study the effect of TCL1A expression on cellular properties. Thus, the murine IL-2 dependent T-cell line CTLL-2 was used instead (138). Although this cell line showed TCR expression, it did not respond to stimulation with CD3/28 beads (data not shown). Instead, these cells responded well to activation through IL-2. As this cytokine activates similar downstream pathways as the TCR (see section 1.1.3), it was used to analyze the cooperation of TCL1A and downstream signaling.

First, survival and proliferation of EGFP only or TCL1A expressing CTLL-2 cells at different IL-2 concentrations was analyzed. CTLL-2 cells were normally maintained at an IL-2 concentration of 300 units (U) per ml. Cell numbers were determined every two days in

cultures with IL-2 concentrations ranging from 0 to 300U per ml over a period of 16 days (Figure 3-30A). Cell numbers dropped with decreasing IL-2 concentrations in both groups and did not show a significant difference. Next, cell numbers were determined in cultures with IL-2 concentrations ranging from 300 to 1000U per ml after two days in culture. Higher IL-2 concentrations showed an effect on cell number in TCL1A transduced CTLL-2 (Figure 3-30B). While the EGFP only group maintained the same cell number at different concentrations, cell numbers of TCL1A expressing CTLL-2 increased with rising IL-2 concentrations.

**Figure 3-30: Cell numbers of TCL1A transduced CTLL-2 at different IL-2 concentrations**  
 CTLL-2 cells were transduced with EGFP only and TCL1A and maintained at different IL-2 concentrations. CTLL-2 cells are normally cultured at a concentration of 300U IL-2 per ml. (A) At lower IL-2 concentrations, cell numbers of CTLL-2 decreased over a period of 16 days. (B) At higher IL-2 concentrations, cell numbers increased in TCL1A transduced over a period of two days.

Next, protein phosphorylation of downstream signaling molecules was evaluated in these cells by PhosFlow analysis of pSTAT5, pAKT and pERK1/2, 24 hours after adding fresh IL-2 to the cultures (Figure 3-31). TCL1A CTLL-2 cells showed increased phosphorylation of AKT (Figure 3-31A) and ERK1/2 (Figure 3-31B) compared to EGFP control cells, whereas no difference was observed in phosphorylation of the key IL-2 signaling protein STAT5 (Figure 3-31C).

**Figure 3-31: Protein phosphorylation in TCL1A transduced CTLL-2 at high IL-2 concentrations**  
 CTLL-2 cells transduced with EGFP only and TCL1A were cultured with 300U and 1000U IL-2 for 24hours and then analyzed for phosphorylation of AKT (S473)(A), ERK1/2 (B) and STAT5 (C). Serum starved CTLL-2 cells were used as negative control and CTLL-2 stimulated with H<sub>2</sub>O<sub>2</sub> served as positive control.

## **4. Discussion**

In this thesis, the oncogenic mechanisms of the TCL1 family have been studied using two murine transplantation models. These genes were introduced into HSCs/HPCs for comparative analyses of their oncogenic potential in general (see section 4.1) or upon targeted expression to cellular compartments (see section 4.2). Additionally, TCL1A variants were introduced into monoclonal T cells to study the cooperation of TCR signaling and TCL1A in mature T-cell transformation (see section 4.3). Both transplantation systems proved to be useful to study different aspects of the TCL1 family and its role in B- and T-cell malignization (see section 4.4).

### **4.1 Comparative analysis of TCL1 family members**

The oncogenic potential of the TCL1 family members TCL1A and MTCP1 in lymphocytes has been described in different transgenic mouse models (see section 1.2.2.3). However, the use of different promoters that drive TCL1 family gene expression in these models, does not allow a direct comparison of the different family members in their oncogenic potential. Additionally, no transgenic model has been described for the third TCL1 family member TML1. The establishment of transgenic mouse models is laborious and hardly feasible for the three family members at once. As syngeneic mouse models offer a good alternative, retroviral vectors were used in this thesis to introduce the TCL1 family genes TCL1A, MTCP1, and TML1 into HSCs/HPCs that were then transplanted into lethally irradiated WT mice (see section 3.2.2). Transduced HSCs/HPCs were not sorted before transplantation to recapitulate a more ‘natural’ pathogenesis, where not all cells carry the same genetic hit. TCL1A and MTCP1 mice predominantly developed B-cell lymphomas after comparable latencies (Figure 3-5). Based on the expression of the mature B-cell markers B220, CD19, and IgM (Table 3-2), a lymphoblastoid morphology (Figure 3-7) and leukemic presentation (Figure 3-8), these tumors were classified as Burkitt-like lymphomas according to the proposed classification of lymphoid neoplasms in mice (140). Thus, TCL1A and MTCP1 are oncogenes with comparable oncogenic potential. Although the exact oncogenic mechanisms of TCL1A remain incompletely resolved, it is known to interact with various key signaling molecules (see section 1.3.1.3). Less is known about the functional aspects of MTCP1, except that it binds AKT. This interaction is approximately 100-fold weaker than the interaction between

TCL1A and AKT (132). TCL1 is thought to enhance AKT activity by dimerization and oligomerization, thereby facilitating AKT transphosphorylation (141). The low affinity for AKT and the lack of a MTCP1 dimerization domain suggests that MTCP1 has a distinct mechanism for AKT activation and/or induces transformation of lymphocytes through separate mechanisms.

Although originally described as T-cell oncogenes, most TCL1A and MTCP1 recipient mice developed B-cell malignancies in the presented model. For TCL1A, this is in accordance with a study of transgenic mice expressing TCL1A in T- and B-cell populations at equal levels that predominantly developed Burkitt-like lymphomas as well (110). However, the only published MTCP1 transgenic model was T cell-specific (81). Therefore, the presented data showed for the first time that MTCP1 is capable of B-cell transformation. The predominant transformation of B cells by TCL1A and MTCP1 is most likely due to accumulation of secondary mutations during B cell-specific diversification processes. Upon activation, peripheral B cells undergo secondary diversification processes, such as somatic hypermutation and class switch recombination, to further enhance antigen binding (60). Somatic hypermutation is achieved by introducing point mutations into the variable regions of immunoglobins resulting in the expression of mutant BCRs. During immunoglobulin class switching the constant region of the immunoglobulin heavy chain is replaced with an alternate region through a process called class switch recombination, a intrachromosomal deletional recombination event requiring double strand breaks. Both processes are known to contribute of deregulated gene expression resulting in transformation of B cells (61). Mature T cells lack similar error-prone mechanisms. It is therefore likely that TCL1/MTCP1-induced T-cell transformation requires more time and is outcompeted by transformation of B cells in the presented model.

The third TCL1 family member TML1 is activated in human T-PLL together with TCL1A. However, it is unknown whether TML1 itself has oncogenic properties. Although TML1 appears to be a weaker oncogene than its two other family members, the presented data provided the first proof for the oncogenic function of TML1 (Figure 3-5). Moreover, its oncogenic function was restricted to T cells (Table 3-1). There is little information on the functional aspects of TML1. Unlike TCL1A, it lacks a dimerization domain and binds AKT with low affinity (141). As it has a weak T cell-specific oncogenic function, TML1 most likely has mechanisms that are different from TCL1A and MTCP1. Interesting is also a 14aa stretch insertion in TML1 as compared to TCL1A, which may point to a phylogenetic evolution from TML1 to the proto-oncogene TCL1 after duplication and deletion of the 14aa

stretch in higher mammals, where TCL1A expression is restricted to. Moreover, retroviral vector-mediated gene transfer bears the risk for insertional mutagenesis that might have contributed to induction or acceleration of tumor development in this model.

## **4.2 Targeting TCL1A to cellular compartments**

In the next part of this thesis, the focus was laid on one of the family members, namely TCL1A, to learn more about the molecular basis of its oncogenic properties. It has been described that TCL1A interacts with different signaling molecules in different cellular compartments (see section 1.3.1.3). However, these studies did not reveal how localization of TCL1A relates to its oncogenic potential. Therefore, expression of TCL1A was targeted to the membrane and the nucleus using a myristoylated variant of TCL1A (myr-TCL1A) and a variant containing a nuclear localization signal (nls-TCL1A), respectively (see section 3.2.4). Interestingly, restricted localization of TCL1A did not impair its oncogenic potential. Similar to the generic TCL1A and MTCP1, both variants predominantly induced Burkitt-like lymphomas (Table 3-4). Survival of myr-TCL1A mice was comparable to the generic TCL1A cohort, whereas nls-TCL1A mice showed a significant reduction in survival (Figure 3-11). Gene expression analyses of these tumors revealed higher similarities between TCL1A and its nuclear variant (Figure 3-14, Figure 3-15). Together this data implicates that TCL1A's predominant oncogenic function relies on its nuclear presence.

Nevertheless, the oncogenic properties of the membrane-bound variant of TCL1A are not impaired compared to the generic TCL1A. Gene expression analyses of TCL1A-, myr-TCL1A- and nls-TCL1A-induced tumors also showed that several signaling pathways are always affected in these tumors, including PI3K/AKT signaling, cell cycle, MAPK signaling, p53 signaling and GPCR signaling pathways (Figure 3-13). These pathways either share pathway components (Table 5-1) or are known to regulate each other. Together these data suggest, that TCL1A has a wide range of molecular mechanisms and is able to ultimately deregulate the same pathways regardless of its cellular localization.

Tumor cells usually show highly deregulated gene expression making it impossible to pinpoint the genetic alteration leading to deregulation of these pathways and ultimately to cellular transformation. Therefore, pre-leukemic B and T cells were sorted from TCL1A, myr-TCL1A and nls-TCL1A HSC/HPC recipient mice 100 days after transplantation to identify early changes in gene expression. Generally, B cells expressing TCL1A variants

showed a significant higher number of deregulated genes than the respective T cells at this time point (Figure 3-16). Moreover, similar pathways were affected in B and T cells (Figure 3-17, Figure 3-18), suggesting that transformation of both cell types is due to deregulation of the same signaling pathways. This data supports the hypothesis that predominant transformation of B cells is due to accumulation of secondary mutations during error-prone, B cell-specific diversification processes, thereby leading to earlier deregulation of cellular pathways.

Interestingly, cell cycle and p53-signaling pathway genes were both affected in B cells and B-cell tumors (Figure 3-13, Figure 3-17), but not in T cells. These pathways might therefore play an important role in the transformation of B cells in the presented model. DNA damage induces the p53-signaling pathway resulting in cell cycle checkpoint activation, thereby promoting either cell survival or death. Deregulation of these pathways has been associated with cellular transformation in general, but has also been detected specifically in B-cell lymphomas as a common feature (142). Cell cycle/p53 pathway genes up-regulated in analyzed B cells and B-cell tumors are Bub1b, Ccna2, Ccnb1, Ccnb2, Mpeg1 and Rrm2 (Table 5-1, Table 5-2). The cyclin genes Ccna2, Ccnb1 and Ccnb2 play an essential role in G2/M cell cycle transition. Overexpression is associated with chromosomal instability and double-strand breaks (143,144). The mitotic checkpoint gene Bub1b normally inhibits cell cycle progression and is more associated with tumor suppressive properties as heterozygous mice display chromosome instability and increased tumor susceptibility (145,146). The observed up-regulation might therefore be a compensatory effect for deregulation of other cell cycle components. The ribonucleotide reductase Rrm2 is important for DNA synthesis in dividing cells and overexpression in mice induces tumor development (147). There is no information on Mpeg1 and its role in cell cycle regulation. Based on this data it is not possible to determine which gene is responsible for cell cycle/p53 signaling deregulation as most of the up-regulated genes have been associated with cellular transformation. TCL1A has been associated with cell cycle interaction through ATM (see section 1.3.1.3). However, this gene is only down-regulated in TCL1A B cells and TCL1A tumors, but not in other cohorts (data not shown). This suggests that TCL1A might interfere with the cell cycle through other components besides ATM. The presented data does not allow drawing similar conclusions about the role of this pathway in the transformation of T cells, as this pathway is not affected in pre-leukemic T cells at the selected time point. This is most likely due to the general lack of early changes in T cells and analyses at later time points might reveal more about the involvement of this pathway. Nevertheless, a few genes were already deregulated in these

cells and they affect the same pathways as the ones seen in pre-leukemic and leukemic B cells, including PI3K/AKT signaling, MAPK signaling pathways and chemokine signaling (Figure 3-13, Figure 3-17, Figure 3-18). Remarkably, one gene is found in five out of the six affected pathways in pre-leukemic T cells, namely AKT1 (Table 5-3). It has been described that TCL1A enhances the kinase activity of AKT by forming hetero-oligomers at the plasma membrane (141). AKT has numerous substrates, thereby regulating survival, growth, cell cycle, proliferation, migration, etc (148). It is therefore likely that it plays a central role in deregulating these pathways in pre-leukemic T cells. However, it seems that the TCL1A-induced activation of AKT is not solely based on the interaction at the plasma membrane, as nls-TCL1A expressing T cells show the same up-regulation of AKT1 (Table 5-3). So far, it has only been described that TCL1A mediates nuclear translocation of AKT (74,119). This data suggests that TCL1A has additional mechanisms for activation of AKT besides oligomerization at the plasma membrane.

Interestingly, the murine TCL1 family members *Mtcp1* and *Tcl1b4* were down-regulated in TCL1A tumors and pre-leukemic TCL1A B-cells, respectively. This might be due cellular compensation of TCL1A overexpression by reducing endogenous expression of TCL1 family members that does not affect expression of the transgene.

### **4.3 Cooperation of TCL1A and TCR signaling**

In a previously described HSC/HPC transplantation model, overexpression of TCL1A variants resulted predominantly in the transformation of B cells, which makes this model unsuitable to study the role of TCL1A in T cells. TCL1A interacts with different signaling molecules along the TCR signaling cascade, suggesting a role of TCR signaling in TCL1A-induced T-cell transformation (see section 1.3.1.3). Newrzela et al showed that T cells can be transformed in a TCR mono-/oligoclonal setting by certain T-cell oncogenes (45), but not in a TCR polyclonal environment (44). This OT-1 TCR monoclonal T-cell model was utilized to study the cooperation between TCL1A and TCR signaling by specifically stimulating the TCR of TCL1A transduced OT-1 T cells in vivo with an OVA peptide. Therefore, mice received transplants of TCL1A transduced OT-1 T cells and were then repeatedly injected with OVA peptide every two weeks. Blood sampling revealed early differences between OVA stimulated TCL1A mice and control mice. In stimulated control mice, the percentage of transplanted T cells decreased in the PB, whereas in TCL1A mice this percentage increased

after an initial decline (Figure 3-23). In vivo imaging showed that these cells are not lost in control mice and rather accumulate in inguinal LNs, abdominal regions and spleen, which was the same for stimulated TCL1A recipient mice (Figure 3-25, Figure 3-26). Thus, this data suggests that T cells retreat to secondary lymphoid organs in a ‘chronically’ stimulated environment. These organs provide pro-survival signals, including cytokines and spMHC peptides that might be essential for maintenance of repeatedly stimulated memory T cells.

The higher percentage of TCL1A expressing T cells in the PB was most likely due to enhanced accumulation of T cells in the presence of TCL1. This is supported by several observations: 1.) Generally higher bioluminescence signals in TCL1A cohorts compared to their unstimulated/stimulated control counterparts (Figure 3-25), 2.) Enrichment of transgene/EGFP expressing T cells in unstimulated TCL1 recipient mice, but not in unstimulated EGFP control mice (Figure 3-23), and 3.) Accelerated enrichment of TCL1A<sup>+</sup> T cells in OVA stimulated TCL1 recipient mice (Figure 3-23). Together this data implicates that enhanced accumulation of TCL1A<sup>+</sup> T cells in these mice is due to increased proliferative activity of these T cells, which is further enhanced by TCR stimulation. More importantly, the presence of TCL1A seemed to be enough to compensate for a TCR signal, as a similar enrichment of EGFP<sup>+</sup> T cells was only observed in stimulated and not unstimulated EGFP only control mice (Figure 3-23). In stimulated control EGFP recipient mice, this enrichment is most likely due to the viral integration that gives these cells an advantage over non-transduced cells, but only in the presence of a TCR stimulus.

The primary aim of this model was to establish, if chronic TCR stimulation has an effect on TCL1A’s oncogenic potential. A significant reduction of survival of stimulated TCL1A mice compared to their unstimulated counterpart clearly demonstrated that chronic TCR engagement facilitated TCL1A-driven transformation (Figure 3-27). The same was observed for the two variants of TCL1A, namely myr-TCL1A and nls-TCL1A (Figure 3-27). This data provides functional proof for the role of TCR stimulation in augmenting the oncogenic properties of TCL1A, most likely by enhancing proliferation of TCL1A expressing T cells. Notable is also the difference in tumor phenotype between unstimulated and stimulated TCL1A mice (Table 3-5). Although a T-cell based transplantation model was used, B-cell tumors arose in a few unstimulated mice. This can be explained by a low percentage of B-cell contamination in the initial transplant (Figure 3-22). However, these tumors did not develop in stimulated mice, thereby suggesting that TCR stimulation drives specific transformation of T cells (or helps in outcompeting the B-cell tumors that would develop at a “basal” rate).

T-cell tumors in these mice often had a CD4 phenotype. This was unexpected as the initial transplant mainly consisted out CD8<sup>+</sup> T cells that specifically recognize the injected OVA peptide. The transgenic OT-1 TCR is MHC class I-restricted thereby limiting OT-1 TCR expression to CD8 T cells. The transgenic TCR is primarily selected in these mice, which leads to preferential outgrowth of transgenic OT-1 TCR expressing CD8 T cells. However, it has been shown that OT-1 thymocytes contain endogenous  $\alpha$  chains that are able to undergo rearrangement and pair with the transgenic  $\beta$  chain, thereby producing CD4 and CD8 T cells with a chimeric TCR (149). These cells usually remain at a very low percentage in the initial transplant, but are not able to recognize the injected OVA peptide (Figure 3-22). A different explanation for the outgrowth of CD4 T-cell malignancies in the presented model is offered by a recent study that has shown that CD8 T cells in OT-1 mice have the capability of differentiating into CD4 T cells that express a functional OT-1 TCR (150). These cells were mostly detected in the large-intestine lamina propria of RAG1<sup>-/-</sup> OT-1 TCR transgenic mice that lack T cells with chimeric TCRs. Adoptively transferred CD4 T cells into WT mice responded to stimulation with OVA peptide. Interestingly, the CD4 tumor phenotype observed in the presented mouse model resembles the T-PLL phenotype in humans (see section 1.2.2.1). Cytologically, these cells resemble medium-sized T lymphocytes seen in T-PLL as well.

Studying OT-1 stimulation in vitro over a long period of time was not feasible. Therefore, for in vitro studies an IL-2 dependent murine T-cell line was used instead. These cells did not respond to TCR stimulation, but to IL-2 stimulation. The IL-2 pathway initiates the same downstream pathways as TCR engagement. In accordance with the data collected in vivo, TCL1A enhanced proliferation of T cells upon activation (Figure 3-30B). At low IL-2 concentrations, TCL1A did not have an anti-apoptotic effect that conferred a survival advantage (Figure 3-30A). The phosphorylation status of the two key signaling molecules AKT1 and ERK1/2 increased with higher IL-2 concentrations in stimulated TCL1A-carrying cells (Figure 3-31). STAT5 is one of the key mediators of IL-2-induced signaling and did not show any difference in its phosphorylation status. Thus, augmented proliferation of TCL1A expressing cells was associated with an enhanced activation of specific signaling molecules. TCL1A enhanced signaling pathways involved in activation and proliferation of T cells in the presented study, but only in the presence of an external stimulus. IL-2 or any other cytokine or co-stimulus would not be sufficient to induce a functional immune response in vivo. Therefore, the TCR plays most likely an important role in mediating / enhancing TCL1A's oncogenic properties by initiating downstream signaling pathways.

The involvement of the TCR in TCL1-driven transformation of T cells suggests the presence of a specific (auto)antigenic drive in T-PLL patients. For some PTCL entities, it has been shown that chronic inflammations often precede lymphoma / leukemia development, e.g. dermatitis prior to cutaneous T-cell lymphomas or expansions of autoimmune cytotoxic T cells prior to T-cell large granular lymphocyte leukemia (77). Inflammatory lesions or a bias in TCR gene usage has not been observed for T-PLL (78,79). This might hint at alternative mechanisms of TCR activation, such as intrinsically autonomous activation.

Retroviral vectors are commonly used for stable integration of genes into the genome of target cells. Despite the initial success in gene therapy, the further use of these vectors in clinical trials has been limited by severe side effects caused by insertional mutagenesis. In our studies, this clinical disadvantage is used to recapitulate secondary genetic hits that often drive the development of cancer. Integration of viral vectors into the host's genome can alter expression of genes around the site of integration that might favor malignant outgrowth. Control mice in these studies did not develop tumors, proving that this side effect is rare. Additionally, integration site analysis of tumors showed that only low numbers of genes are affected and classified in pathways, indicating that the introduced oncogene alone is responsible for cellular transformation (Table 3-7, Table 3-8). Although similar pathways are affected, there is no statistical overrepresentation that would allow drawing sound conclusions.

Besides the generic TCL1A, its variants myr-TCL1A and nls-TCL1A were also used in the described T-cell model. The effect of stimulation on survival was comparable to the generic TCL1A (Figure 3-27). There was no significant difference in survival between the different variants in the T-cell model, although nls-TCL1A showed reduced survival in the HSC/HPC model compared to the other variants (Figure 3-11). This suggests that TCL1A's nuclear presence might be more important for transformation of B cells than for T cells.

It should be noted that mice often developed ascites in this model as a side effect of repeated i.p. injections over a long period of time and had to be sacrificed before tumor development. This was not cohort-related as it was observed for stimulated and unstimulated control and TCL1A mice. To prevent this side effect and improve the system, it might be necessary to lower the frequency of injections.

#### **4.4 General considerations for the use of HSCs/HPCs or TCR monoclonal T cells as target cells in syngeneic mouse models for lymphoma/leukemia studies**

In the presented syngeneic mouse models, grafts from mice with the same genetic background were genetically manipulated using retroviral vectors. Most studies that work with these models use BM-derived HSCs/HPCs as donor cells. Retroviral transduction and transplantation of HSCs/HPCs is an efficient method to introduce transgenes into lymphocytes without altering these cells directly. Additionally, this has the advantage that the hematopoietic system is fully developed and functional, recapitulating a more “natural” tumorigenesis in immunocompetent hosts. This model is highly suitable for comparative analyses of oncogenic properties. In the case of TCL1A and its family members, B cells are predominantly transformed, making this a useful model for B-cell studies, but not for studying T-cell transformation. Interestingly, histological and cytological analysis showed that B-cell tumors induced in the HSC/HPC model had a larger and more immature morphology than the ones that developed in the T-cell model. This difference was not observed based on the flow cytometric analysis alone. Thus, using HSCs/HPCs or mature lymphocytes made a difference for the phenotype of the induced B-cell tumors.

Studying mature T-cell malignancies in mice has been challenging, as there is no promoter available that targets transgene expression specifically to mature T cells (151). In the presented HSC/HPC model, only immature T-cell tumors developed and were mostly outcompeted by the outgrowth of B-cell malignancies. Using mature T cells as target cells for retroviral transduction has been limited by their resistance to transformation by oncogenes, including TCL1A (44). However, using TCR monoclonal instead of TCR polyclonal T cells circumvented this effect (45). The TCR monoclonal system offers the possibility to study the role of the TCR in cellular transformation. There are several different transgenic TCR models that allow specific stimulation of CD4 and CD8 T cells, such as OT-1, OT-2 or P14. Similarly, this could be done for B cells and BCR stimulation, e.g. using MD4 transgenic B cells that specifically recognize hen egg lysozyme. However, these models represent rather simplified approaches to study the pathogenesis of mature T- or B-cell tumors. Immunodeficient hosts and TCR monoclonal lymphocytes do not represent a “natural” environment, but they offer a good starting point to dissect the complex course of cellular transformation. Next, this model can be further adapted by mixing TCR polyclonal T cells to

the TCR monoclonal transplant or by using Nude mice as recipients that have functional B cells and only lack T cells.

## **4.5 Conclusions and Outlook**

The presented study covers different aspects on the function of TCL1 oncogene family members. First, it was shown that TCL1A and MTCPI share a similar oncogenic capacity, whereas TML1 is a weak oncogene with low penetrance in our systems. Currently, primary T-PLL cases are analyzed for expression frequency of these three oncogenes in our laboratory.

Next, it was shown that nuclear localization of TCL1A reduced survival of recipient mice compared to the generic TCL1A protein and a membrane-localizing variant. Gene expression data revealed an important role of p53 signaling and cell cycle genes in the transformation of B cells. Gene expression data collected from this study is currently compared to gene expression data from TCL1A transgenic mice at different time points before tumor development.

In the last part of this thesis a new *in vivo* model was established to specifically stimulate the TCR of TCR monoclonal T cells *in vivo*. The data clearly show that TCL1A-driven transformation is facilitated by repeated TCR stimulation, thereby demonstrating that there likely is a pro-leukemogenic cooperation between TCL1A and TCR signaling. To further analyze this synergy, signaling dosages of TCL1A and TCR are currently analyzed in human CTCL cell lines by titrating TCL1A levels in a Tet-ON TCL1A-inducible system and by titrating TCR activation through blocking antibodies (OKT3 or 15E8). The aim of this experiment is to determine how these signals compensate for each other, e.g. if a higher expression of TCL1A can compensate for high-avidity TCR engagement. For further *in vivo* studies polyclonal T cells are added to the OT-1 T cell transplant to test if the additional TCR stimulus allows TCL1A transduced T cells to overcome clonal competition. Furthermore, TCL1 transgenic mice are crossbred with CD3-deficient and MHC-deficient mice to address the requirement of TCR signaling input in TCL1-mediated oncogenesis.

The antigen receptor plays a central role in T- and B-cell development, function and survival. The clinical and therapeutic importance of the BCR has been well described for B-cell malignancies (152). In the recent years, specific inhibitors of BCR signaling molecules, such as PI3K or Bruton's tyrosine kinase (BTK), have been approved for the treatment of B-cell

lymphomas / leukemias and have shown promising clinical results (153,154). For the treatment of PTCL, an inhibitor of the TCR signaling kinase mTOR showed successful results in ongoing clinical trials as well (155). The suitability of interleukin-2-inducible T-cell Kinase (ITK) as an effective drug target for PTCL is currently investigated, but likely its role in T cells is not congruently reflected by BTK in B-cells and the derived tumors (156). These studies emphasize the potential of treatment approaches targeting antigen receptor signaling and the demand for a detailed understanding of TCR involvement in PTCL pathobiology.

## 5. Appendices

### 5.1 Abbreviations

AICD	Activation-induced cell death
AITL	Angioimmunoblastic T-cell lymphoma
APC	Antigen presenting cell
ALCL	Anaplastic large cell lymphoma
ATM	Ataxia telangiectasia mutated
BM	Bone marrow
BSA	Bovine serum albumin
CAR	Chimeric antigen receptor
CCL	Chemokine with C-C motive
CD	Cluster of differentiation
CDR	Complementarity determining region
CLL	Chronic lymphocytic leukemia
CLP	Common lymphoid progenitor
CTL	Cytotoxic T-lymphocyte
DMEM	Dulbecco's modified eagle medium
DMSO	Dimethyl sulfoxide
DN	Double negative
DNA	Deoxyribonucleic acid
DP	Double positive
E.coli	Escherichia coli
EDTA	Ethylenediaminetetraacetic acid
EGFP	Enhanced green fluorescent protein
ER	Endoplasmic reticulum
FACS	Fluorescence activated cell sorting
FBS	Fetal bovine serum
FC	Flow cytometry
FELASA	Federation of European Laboratory Animal Science Associations
GPCR	G protein-coupled receptor
HBSS	Hanks balanced salt solution
HE	Hematoxylin/eosin
HEPES	Hydroxyethylpiperazineethanesulfonic acid
HPC	Hematopoietic progenitor cell
HSC	Hematopoietic stem cell
ICFC	Intracellular Flow Cytometry
IFA	Incomplete Freund's adjuvant
i.p.	Intraperitoneal
i.v.	Intravenous
IFN- $\gamma$	Interferon $\gamma$

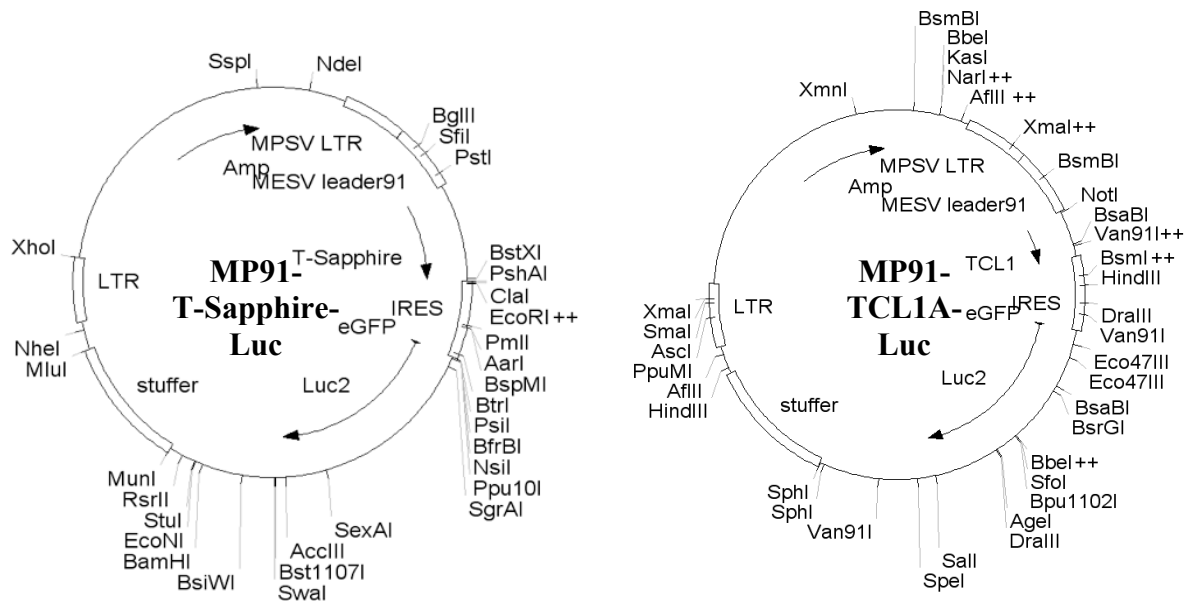

Ig	Immunoglobulin
IL	Interleukin
ITAM	Immunoreceptor tyrosine-based activation motifs
IVC	Individually ventilated cages
LN	Lymph node
LTR	Long terminal repeats
M	Molar
MACS	Magnetic activated cell sorting
MSA	Mouse Serum Albumin
MTCP1	Mature T-cell proliferation 1
MTCL	Mature T-cell leukemias/lymphomas
MHC	Major histocompatibility complex
MYC	Myelocytomatosis oncogene
NK	Natural killer
OVA	Ovalbumin
PTCL	Peripheral T-cell leukemias/lymphomas
RAG	Recombination activating gene
ROI	Region of interest
rpm	Rounds per minute
RPMI	Roswell Park Memorial Institute
RSD	Relative standard deviation
SP	Single positive
spMHC	Self-peptide/Major histocompatibility complex
STAT	Signal transducer and activator of transcription
SV40	Simian virus 40
Th	T-helper cells
TCL1A	T-cell leukemia/lymphoma 1
TCR	T-cell receptor
TGF- $\beta$ 1	Transforming growth factor- $\beta$ 1
TML1	TCL1A/MTCP1-like 1
T-PLL	T-cell prolymphocytic leukemia
v/v	Volume/Volume
WB	Western Blot
WBC	White blood count
WHO	World Health Organization

## 5.2 Plasmid Maps

\* Representative plasmid card for MTCP1, TML1, myr-TCL1A, and nls-TCL1A.

**Figure 5-1: Plasmid maps.**

### 5.3 Lists of differently expressed genes

		TCL1A	myr-TCL1A	nls-TCL1A
Chemokine Signaling Pathway	↑	Cxcl2, Gng12	Cxcl2, Gng12	Cxcl2, Gng12
	↓	Ccr7, Akt3	Ccr7, Akt3	Ccr7, Akt3
Cell Cycle	↑	Bub1b, Bub1, Ccna2, Chek1, Ccnb1, Ccnb2, Tfdp1, Cdkn1a, Cdc20, Mpeg1, Plk1, Cdc25c	Bub1b, Bub1, Wee1, Ccna2, Chek1, Ccnb1, Ccnb2, Tfdp1, Cdkn1a, Cdc20, Mpeg1, Plk1, Cdc25c	Bub1b, Wee1, Ccna2, Ccnb1, Ccnb2, Tfdp1, Cdc20, Plk1
p53 Signaling	↑	Chek1, Cdkn1a, Ccnb1, Ccnb2, Cdk1, Rrm2	Chek1, Cdkn1a, Ccnb1, Ccnb2, Cdk1, Rrm2	Ccnb1, Ccnb2, Cdk1, Rrm2
	↓	-	Ddb2	Ddb2
PI3K-AKT-mTOR Signaling Pathway	↑	Gng12, Cdkn1a	Gng12, Cdkn1a	Gng12
	↓	Itgam, Il4ra, Akt3	Itgam, Akt3	Il4ra, Akt3
miRNA regulation of DDR	↑	Cdkn1a, Ccnb1, Chek1, Cdk1, Cdc25c, H2afx, Ccnb2	Cdkn1a, Ccnb1, Chek1, Cdk1, Cdc25c, H2afx, Ccnb2	Ccnb1, Cdk1, H2afx, Ccnb2
	↓	-	Ddb2	Ddb2
MAPK Signaling Pathway	↑	Stmn1, Hspa5,	Stmn1, Hspa5	-
	↓	Tgfbr2, Ppp3cc, Akt3	Ppp3cc, Akt3	Tgfbr2, Ppp3cc, Akt3
Purine metabolism	↑	Rrm2	Rrm2, Prps2, Pde8a	Rrm2, Pde8a
	↓	Pde4d, Polr3e	Pde4d, Polr3e	Polr3e
Non-odorant GPCRs	↑	Ccr12, Lphn2	Ccr12	Lphn2
	↓	Ccr7, Gpr174	Ccr7, Gpr174, S1pr1	Ccr7, Gpr174, S1pr1
TGF-beta Receptor Signaling	↑	Cd44, Atf3, Tfdp1, Cdkn1a, Ccnb2	Cd44, Atf3, Tfdp1, Cdkn1a, Ccnb2	Atf3, Tfdp1, Ccnb2
	↓	Tgfbr2, Crebbp	-	Tgfbr2, Crebbp
Ca2+ Regulation	↑	Prkar2b, Gng12	Prkar2b, Gng12	Prkar2b, Gng12
	↓	-	Itpr2	Itpr2

Table 5-1: List of pathway genes up-regulated (↑) or down-regulated (↓) in at least two of three cohorts: TCL1A, myr-TCL1A and nls-TCL1A

		TCL1A	myr-TCL1A	nls-TCL1A
Cell Cycle	↑	Bub1b, Ccna2, Gadd45a, Ccnb1, Ccnb2, Mpeg1	Bub1b, Wee1, Ccna2, Gadd45a, Ccnb1, Ccnb2	Ccna2, Gadd45a, Ccnb1, Mpeg1
MAPK Signaling Pathway	↑	Gadd45a, Gna12, Mapkapk2, I11a	Gadd45a, Gna12, Mapkapk2	Gadd45a, Gna12, Mapkapk2, I11a
	↓	-	Ppm1b	Ppm1b
PI3K-AKT-mTOR Signaling Pathway	↑	Creb3l2	Creb3l2	Creb3l2
	↓	Itgam, Ppp2r5c	Itgam	Itgam, Ppp2r5c
Adipogenesis genes	↑	Pparg, Gadd45a, Ahr	Gadd45a, Ahr	Pparg, Gadd45a, Ahr
Regulation of Actin Cytoskeleton	↑	Gna12	Gna12, Ssh2	Gna12, Ssh2
Purine metabolism	↑	Rrm2, Entpd1	Rrm1, Rrm2	Entpd1
	↓	Pde4d, Nme2	-	Pde4d, Nme2
p53 Signaling	↑	Ccnb1, Ccnb2, Gadd45a, Rrm2	Ccnb1, Ccnb2, Gadd45a, Rrm2	Ccnb1, Gadd45a
mRNA processing	↓	Park7	-	Park7
miRNA regulation of DDR	↑	Gadd45a, Ccnb1, H2afx, Ccnb2	Gadd45a, Ccnb1, H2afx, Ccnb2	Gadd45a, Ccnb1

**Table 5-2: List of pathway genes up-regulated (↑) or down-regulated (↓) in at least two of three cohorts: TCL1A, myr-TCL1A and nls-TCL1A B cells**

		TCL1A	myr-TCL1A	nls-TCL1A
Chemokine Signaling Pathway	↑	Ccr8	Ccr8, Akt1	Ccr8, Akt1
MAPK Signaling Pathway	↑	-	Gna12, Akt1, Stk3, Mapkapk2	Gna12, Akt1, Stk3, Mapkapk2
Kit Receptor Signaling Pathway	↑	Grb7	Grb7, Akt1, Spred1	Grb7, Akt1, Spred1
Androgen Receptor Signaling Pathway	↑	-	Akt1	Akt1
PI3K-AKT-mTOR Signaling Pathway	↑	-	Itgax, Akt1, Ppp2r1a	Itgax, Akt1, Ppp2r1a
G1 to S cell cycle control	↑	-	Tfdp1, Mcm2, Pola2	Tfdp1, Mcm2, Pola2

*Table 5-3: List of pathway genes up-regulated (↑) or down-regulated (↓) in at least two of three cohorts: TCL1A, myr-TCL1A and nls-TCL1A T cells*

## 5.4 Lists of retroviral integration sites

Tumor	Chr	Location	Type	Gene Symbol	Distance	Start	End	OR	Hit

**Table 5-4: List of retroviral integration sites of T-cell tumors induced by TCL1A in unstimulated mice**

*Tumor: Tumor sample. Chr: Mapped chromosome. Location: Genome location. Type: Closest (c) and surrounding (s) genes. Distance: Distance between integration and gene start. Start: Gene start. End: Gene end. OR: Relative orientation of integrated vector (F: forward, R: reverse). Hit: Hit in gene.*

**Table 5-5: List of retroviral integration sites in T-cell tumors induced by TCL1A in stimulated mice**  
Tumor: Tumor sample. Chr: Mapped chromosome. Location: Genome location. Type: Closest (c) and surrounding (s) genes. Distance: Distance between integration and gene start. Start: Gene start. End: Gene end. OR: Relative orientation of integrated vector (F: forward, R: reverse). Hit: Hit in gene.

Tumor	Chr	Location	Type	Gene Symbol	Distance	Start	End	OR	Hit

**Table 5-8: List of retroviral integration sites in T-cell tumors induced by nls-TCL1A in unstimulated mice**

*Tumor:* Tumor sample. *Chr:* Mapped chromosome. *Location:* Genome location. *Type:* Closest (c) and surrounding (s) genes. *Distance:* Distance between integration and gene start. *Start:* Gene start. *End:* Gene end. *OR:* Relative orientation of integrated vector (F: forward, R: reverse). *Hit:* Hit in gene.

**Table 5-9: List of retroviral integration sites induced by nls-TCL1A in stimulated mice**  
Tumor: Tumor sample. Chr: Mapped chromosome. Location: Genome location. Type: Closest (c) and surrounding (s) genes. Distance: Distance between integration and gene start. Start: Gene start. End: Gene end. OR: Relative orientation of integrated vector (F: forward, R: reverse). Hit: Hit in gene.

## **Danksagung**

Ich möchte mich an dieser Stelle ganz herzlich bei allen bedanken, die mich bei dieser Arbeit in jeglicher Art unterstützt haben.

Zunächst möchte ich mich bei Dr. Marco Herling bedanken, der mir die Bearbeitung dieser Arbeit ermöglicht hat. Auch möchte ich mich bei ihm für die Betreuung, Hilfestellung und engagierte Förderung bedanken. Für die nette Zusammenarbeit und Unterstützung danke ich auch der Arbeitsgruppe Herling, insbesondere Dr. Alexandra Schrader, Dr. Elena Vasyutina und Petra Mayer.

Prof. Dr. Jens Brüning danke ich für die Bereitschaft meine Doktorarbeit extern zu betreuen. Zudem möchte ich ihm und Dr. Hildegard Büning für hilfreiche Diskussionen während meiner Committee Meetings danken.

Ganz besonders möchte ich mich auch bei Dr. Sebastian Newrzela für die motivierende Betreuung bedanken und dafür, dass er stets ein offenes Ohr für mich hatte. Mein Dank geht auch an die Mitglieder der Arbeitsgruppe Newrzela: Dr. Benjamin Rengstl, Dr. Tim Heinrich, Dr. Frederike Schmid, Smaro Soworka, Robin Wistinghausen, Christian Weiser, Juliane Wannemacher, Anna Stemann und Dr. Ji-Hee Yi. Ich danke euch für die tolle Zusammenarbeit, das angenehme Arbeitsklima und eure enorme Hilfsbereitschaft!

Prof. Dr. Martin-Leo Hansmann danke ich dafür, dass er mir die Möglichkeit gegeben hat am Dr. Senckenbergischen Institut für Pathologie in Frankfurt meine Forschungsarbeit durchführen zu können. Ihm und Dr. Sylvia Hartmann danke ich auch für die Begutachtung histologischer Präparate.

A very special thanks goes to my husband Shaun. Thank you for your support, your patience, and always making me laugh!

Ein großes Dankeschön gebührt meiner Familie und Freunden, und vor allem meinen Eltern, die mir immer zur Seite standen. Besonders möchte ich mich auch bei meiner Schwester Anna bedanken, auf deren Hilfe ich mich immer verlassen konnte und die immer für mich da war.

## Erklärung

Ich versichere, dass ich die von mir vorgelegte Dissertation selbständig angefertigt, die benutzten Quellen und Hilfsmittel vollständig angegeben und die Stellen der Arbeit – einschließlich Tabellen, Karten und Abbildungen –, die anderen Werken im Wortlaut oder dem Sinn nach entnommen sind, in jedem Einzelfall als Entlehnung kenntlich gemacht habe; dass diese Dissertation noch keiner anderen Fakultät oder Universität zur Prüfung vorgelegen hat; dass sie – abgesehen von unten angegebenen Teilpublikationen – noch nicht veröffentlicht worden ist sowie, dass ich eine solche Veröffentlichung vor Abschluss des Promotionsverfahrens nicht vornehmen werde. Die Bestimmungen der Promotionsordnung sind mir bekannt. Die von mir vorgelegte Dissertation ist von Prof. Dr. Jens Brüning und Dr. Marco Herling betreut worden.

# Curriculum Vitae

## Persönliche Daten

Name: Kathrin Warner  
Geburtsdatum: 19.08.1985  
Geburtsort: Düsseldorf  
Familienstand: verheiratet  
Staatsangehörigkeit: deutsch  
Email: kathrin.warner@uk-koeln.de

## Ausbildung

Seit 11.2015      Wissenschaftlicher Mitarbeiter an der Uniklinik Frankfurt, verantwortlich für die Implementierung eines digitalen Pathologiesystems

07.2011-10.2015      Promotion an der Uniklinik Köln in der Arbeitsgruppe von Dr. Marco Herling zum Thema „Proficiency and mechanisms of perturbation of mature T-cell homeostasis by the TCL1 family“

11.2009-01.2011      Praktikum im Terry Fox Laboratory am BC Cancer Research Center in Vancouver (Kanada) zum Thema „Lymphoid progenitors in normal mouse lymph nodes“

01.2009-08.2009      Praktikum in der Abteilung Tumorummunologie an der Radboud Universität Nijmegen (Niederlande) zum Thema „ Knockdown of DC-STAMP to explore its function in dendritic cells“

09.2008-08.2010      „Master of Science“ Studium der medizinischen Biologie an der Radboud Universität Nijmegen (Niederlande)

04.2008-08.2008      Praktikum in der Abteilung für Orthodontie und Orale Biologie an der Radboud Universität Nijmegen (Niederlande) zum Thema „Effects of high and low molecular weight hyaluronic acid on gel contraction“

09.2005-09.2008      „Bachelor of Science“ Studium der medizinischen Biologie an der Radboud Universität Nijmegen (Niederlande)

2000-2005	Städtisches Gymnasium Straelen, Straelen Allgemeine Hochschulreife
1996-2000	Annette-von-Droste-Hülshoff Gymnasium, Düsseldorf
