Berichterstatter/in: Prof. Dr. Martin Hülskamp
Prof. Dr. Ute Höcker

Prüfungsvorsitzender: Prof. Dr. Kay Hofmann

Tag der mündlichen Prüfung: 1 Dezember 2015

Kurzzusammenfassung

Die Endosomal Sorting Complex Required for Transport (ESCRT) - Maschinerie besteht aus vier Komplexen, ESCRT-0-III. Diese sortieren am späten Endosomen mono-ubiquitinierte Proteine in intraluminale Vesikel, was zur Bildung eines Multivesikulären Körpers (MVB) führt. Der MVB wird zur Vakuole transportiert, wo sein Inhalt degradiert wird (Katzmann et al., 2001; Babst et al., 2002a,b). In *Arabidopsis thaliana* führt der Verlust der ESCRT-I-Komponente ELCH zu Cytokinese-Defekten (Spitzer et al., 2006); während die Expression einer dominant-negativen Form der ESCRT-III-Komponente SKD1 zum Verlustes der Vakuole und nachfolgend zum Zelltod führt (Shahriari et al., 2010a).

In dieser Arbeit wird die Funktion des pflanzenspezifischen ELCH-Interaktors *CELL DEATH RELATED FYVE/SYLF DOMAIN CONTAINING 1 (CFS1)* und seinen Einfluss auf die ESCRT-Maschinerie analysiert. CFS1 ist ein Phosphatidylinositol-3-Phosphat- und Actin-bindendes Protein (Herberth, 2012). Die *cfs1* Mutanten imitieren Läsionen in der ersten älteste Blatt, das auf die nächste älteste Blatt verbreiten. Es konnte gezeigt werden, dass die *cfs1*-Mutanten unter normalen Bedingungen milde Autoimmun-Symptome zeigen. Genetische Analysen zeigen das der Zelltod in *cfs1* keinen funktionalen ESCRT-I-Komplex voraussetzt, dennoch mildert der Verlust von CFS1 den Cytokinese-Defekt der *elch*-Mutante, was einen Einfluss auf die ESCRT-I-Funktion nahelegt. Aufgrund einer Reduktion des Autophagosomen-Abbaus akkumuliert die *cfs1*-Mutante im Laufe ihres Lebens Autophagosomen. Während die Pflanze altert, triggeren die akkumulierten Autophagosomen fälschlicherweise die Effektor-getriggerte Immunität, was in seiner Konsequenz zum Zelltod in *cfs1* führt. Da die ESCRT-Maschinerie am Transport von Autophagosomen zur Vakuole beteiligt ist (Gao et al., 2015; Katsiarimpa et al., 2013; Spitzer et al., 2015) und CFS2, ein CFS1 Homolog mit ATG8 interagiert (Stark et al., 2006), legen die Ergebnisse dieser Arbeit nahe, dass CFS1 zusammen mit CFS2 eine Funktion bei der Bindung von reifen Autophagosomen an MVBs übernimmt. An den MVBs vermittelt die ESCRT-Maschinerie dann die Fusion von Autophagosomen und MVBs für den nachfolgenden Transport zur Vakuole.

Abstract

The Endosomal Sorting Complex Required for Transport (ESCRT)-complex is composed of four complexes, ESCRT-0-III. They sequentially act on a late endosome to sort mono-ubiquitinated transmembrane proteins into the intraluminal vesicle, forming of a multivesicular body (MVB) that is delivered to vacuole for degradation (Katzmann et al., 2001; Babst et al., 2002a,b). In *Arabidopsis thaliana*, the loss of an ESCRT-I component, *elch* displays a cytokinesis defect (Spitzer et al., 2006); while a dominant negative expression of an ESCRT-III component results in cell death due to vacuolar loss (Shahriari et al., 2010a).

In this work, the function of a plant-specific ELCH-interactor, *CELL DEATH-RELATED FYVE/SYLF DOMAIN CONTAINING 1* (*CFS1*) and its influences on the ESCRT-complex function are investigated. *CFS1* is a phosphatidylinositol 3-phosphate- and actin-binding protein (Herberth, 2012). The *cfs1* mutants mimic lesions in the first eldest leaf that propagate to the next eldest one. Genetic analyses have demonstrated that cell death in *cfs1* does not require a functional ESCRT-I component; nevertheless, the loss of *CFS1* alleviates *elch*-cytokinesis defect, suggesting its influence on the ESCRT-I function. Further analyses reveal that *cfs1* accumulates autophagosomes throughout its lifespan due to a decrease in autophagosome degradation, suggesting that as the plant ages, the cumulated autophagosomes falsely trigger effector-triggered immunity that executes cell death in *cfs1*. As the ESCRT-complex has been demonstrated to be involved in the delivery of autophagosomes to vacuole (Gao et al., 2015; Katsiarimpa et al., 2013; Spitzer et al., 2015) and *CFS1* homolog, *CFS2* reportedly interacts with ATG8 (Stark et al., 2006), it can be postulated from the results of this work that *CFS1* alone or together with *CFS2* function in sequestering mature autophagosomes onto MVBs. At the MVBs, the ESCRT-complex then mediates the fusion of autophagosome and MVB for subsequent delivery to vacuole.

For *Mummy*,
my anchor, advisor, therapist and knight in shining armor!

And for *Papa*,
in loving memories (10 May 1952 - 1 November 2003).

Acknowledgements

My deepest gratitude goes to *Prof. Dr. Martin Hülskamp* for allowing me the opportunity to work on this project in his lab. I am truly grateful for having been able to spend these last four years with and being one of his lab members. My sincere gratitude goes to *Prof. Dr. Ute Höcker* for accepting to be my second referee in the examination on a rather short-notice. And also for all her encouragement at the very beginning of my graduate study and her comments and suggestions in the progress seminar throughout the year. I also avail this opportunity to thank *Prof. Dr. Kay Hofmann* for kindly accepting to chair the examination.

My sincere gratitude goes to my supervisor, *Dr. Swen Schellmann* for his time and patience. I genuinely appreciate his support and all the thought-provoking discussion. A huge thank you to *Dr. Stefanie Herberth* for her help ever since I first began to work on this project until the very moment I am handing in this thesis. I could only have completed this with my sanity still intact because of her support and encouragement! The same goes to *Britta Müller*, not only for her beautiful sections and TEM pictures but also for her support and encouragement on a professional and personal levels. I am truly grateful for having her next to me in the office and for our break on the balcony.

Thank you *Manuel Osuna-Martinez* and *Julian Müller*, who have produced great results during the internship and BSc thesis. Their findings have saved me time and helped piecing my data together in the discussion. I would like to thank the institute photographer, *Siegfried Werth* who has taken all the photographs of the mutants, particularly his willingness to do so on a short-notice; and the *gardeners* who have put up with my frequent 'bunny invasion' in the greenhouse.

I am extremely grateful to *Jane Parker* of the Max-Planck Institute for Plant Breeding, Cologne for providing the *eds1-2* and SA-biosynthesis mutants, as well as her comments and suggestions she gave during the many SFB635 meetings. Considerable findings in this work only came about because of her the

insights she readily offered. I am also grateful to *Moritz Nowack* of the Ghent University for sharing some of the unpublished developmentally-related cell death marker genes. I also like to thank *John Mundy* of the University of Copenhagen for providing the *laz1-5* and *nahG* seeds.

Thank you to all former and current *Hülskamp lab members*. They have been extremely helpful and supportive in all things science-related and otherwise. Especially, the sweetest & greatest *Alexandra Steffens*, who is *literally, the best office and lab mate anyone could ever ask for*. Thank you for all the help with *everything* lab and non-lab related. I am so thankful for her voluntarily taking her time to teach me and discuss with me. Our late night in the lab or the office are one of the most enjoyable time during the course my PhD.

Another thank you goes to *Marc Jakoby* for his help with the day-to-day work in the lab, suggestions and spontaneous discussions. And most importantly, for all the time that he '*lent*' me the lab gears on his bench. For the beautiful endomembrane system artwork, I would like to thank *Lisa Stephan* - without her original svg file, I would have taken weeks to generate and learn how to use Inkscape for this thesis! Thank you *Uschi Claßen* who bore with my immoderate plastic, chemical and other lab materials consumption in the last few months without a single complaint and for always encouraging me in the time that I needed it most. Also, another big thank you to the wonderful lab manager/waste queen, *Birgit Kernebeck* for her support and understanding during my writing period; and to *Christina Maria Franck & Aurélien Boisson-Dernier* who made my other-than-submission-deadline distress very short-lived; and to *Jessi Pietsch, Ilka Schultheiß, Heike Wolff, Hemal Bhasin and Divykriti Chopra* for always having their ears to let me talk my worries away; and to *Benjamin Jaegle* for his suggestions about dealing the thesis writing and not-quite-being-on-schedule stress.

Ganz herzlichen Dank an *Frauke & Heiner* für Eure Unterstützung, insbesondere in der Schreibenphase. Ich bin sehr dankbar für die Einladungen zu den Familienfeiern und Weihnachtsfesten, sowie für die '*Köln-ist-mir-zu-viel-deswegen-muss-ich-sofort-wegfahren*' oder '*Ich-brauche-Zeit-und-Ruhe-damit-*

ich-schreiben-kann' Wochenenden, die ich bei Euch verbringen durfte. Eure Unterstützung, Ermutigung und Beratung haben mich sehr motiviert.

Ich bedanke mich bei meiner Mitbewohnerrin *Eva Hahnrrath*. Ohne Dich hätte ich in der Schreibenphase abgebrochen und verrückt geworden!!

I am forever grateful for my Bachelor thesis advisor *Assist. Prof. Dr. Nathinee Panvisavas* for seeing my potential even when I did not think I had any. Her advice and words of wisdom in how to work are precious, and I have only begun to understand how exceptional they were.

Special thanks to the girls, *Hnoon Pantila Petcharat, Amanda van der Meeren and 'Mermer' Tammarat Piansawan* and the other ones on the other side of the world, *Lek Tuengtem* and *Khim Puttiya* for their unwavering friendship and support whether in time of joy, happiness, headache or heartbreak.

And lastly, a big thousand times thank you to my family, including the extended one: my sister *Pang Amornpun*, my aunt *Taksina* who has been like a second mother to me, my cousin *Noon Dutsadi* who often time is like my big sister. Thank you for your encouragement and for being a constant figure in my life!

RNS	Reaction nitrogen species
RNS3	RIBONUCLEASE 3
ROS	Reactive oxygen species
RT-qPCR	Real-time quantitative reverse transcription PCR
RuBisCO	RIBULOSE-1,5-BISPHOSPHATE CARBOXYLASE/OXYGENASE
SA	Salicylic acid
SAR	Systemic acquired resistance
SDS	Sodium dodecyl sulfate
sec	seconds
SH3P2	SH3 DOMAIN CONTAINING PROTEIN 2
SH3YL1	SH3 domain containing Ysc84-like 1
SID2	SALICYLIC ACID INDUCTION DEFICIENT 2
SKD1	SUPPRESSOR OF K ⁽⁺⁾ TRANSPORT GROWTH DEFECT1
SNARE	Soluble N-ethylmaleimide-sensitive factor Attachment protein RE- ceptor
SYLF	SH3YL1, Ysc84p/Lsb4p, Lsb3p, plant FYVE proteins
SYP	SYNTAXIN OF PLANTS
TEM	Transmission electron microscopy
TIR	Toll-interleukin-1-receptor domain
U	units
UGT74E2	URIDINE DIPHOSPHATE GLYCOSYLTRANSFERASE 74E2
UPR	unfolded protein responses
UPS	ubiquitin/26S proteasome system
UTR	untranslated region

List of Abbreviations

VPE	VACUOLAR PROCESSING ENZYME
vps	vacuolar protein sorting
VSP2	VEGETATIVE STORAGE PROTEIN2
Vta1	Vps20-associated 1
Ws-2	<i>Arabidopsis thaliana</i> ecotype Wasilewskaja
YAB	Ysc84 actin binding
YFP	Yellow fluorescent protein

The following nomenclature is used for plants:

- Gene name is written in italics; protein products of the gene in capitals without italics
- Wild-type allele of the gene is written in capitals; mutant allele in lower case letters
- Different alleles of the same gene is indicated by an Arabic number following a hyphen

The following nomenclature is used for yeast:

- Gene name is written in italics. In case of a gene name defined by mutation, dominant trait is written in capitals and recessive in lower case letters.
- Protein product is written as its gene without italics and followed by the suffix 'p'.

1. Introduction

1.1 Cell death as a means to flourish and survive

Cell death is a set of biochemical and molecular processes that lead up to a permanent termination of vital cellular activities (Galluzzi et al., 2014). When cell death occurs in a regulated manner, it facilitates the process of living. Multicellular organisms use cell death as a fundamentality of development and adaptation, including embryogenesis, shape sculpturing, and response to pathogen invasion or other abiotic stimulants (Fuchs and Steller, 2011). The execution of cell death in these processes differs in their natures and can be distinguished by the morphology of the cell corpse, which has been used as a basis for cell death classification (Reape et al., 2008; Galluzzi et al., 2012; van Doorn et al., 2011). Nevertheless, the corpse morphology unavoidably conceals the finer details of the molecular, biochemical or even functional processes that bring about cell death (Galluzzi et al., 2012).

1.1.1 Modes of cell death in animals

Research on cell death in the animal field has been more extensive and defined than in the plant field. Death that results from an unpreventable source is considered an *accidental cell death* (ACD) and can initiate a *regulated cell death* (RCD) event. RCD is controlled and preventable, including death during developmental processes that are collectively termed *programmed cell death* (PCD) (Galluzzi et al., 2014).

RCD mode can now be assigned to the associated biochemical and molecular basis (Galluzzi et al., 2012). *Apoptosis* is the most comprehensive form of cell death that is characterized by the fragmentation of the cell into smaller apoptotic bodies that are eventually engulfed by phagocytes. This mode can be initiated by intrinsic or extrinsic stimuli and is executed by caspase activity and pore-forming activity of the B-cell CLL/lymphoma 2 (BCL2) family mem-

1.1 Cell death as a means to flourish and survive

bers (Galluzzi et al., 2014). Opposite to apoptosis is *regulated necrosis* (Vanden Berghe et al., 2014), also termed *necroptosis* (Kaczmarek et al., 2013), that occurs when the cell dies when or while caspase activity is suppressed (Galluzzi et al., 2012). *Autophagic cell death* is another mode of cell death that does not depend on caspase nor BCL2 members activity but on autophagy-mediated lysosome loading. It is distinguished by the presence of a massive lysosome in the cell (Galluzzi et al., 2012) and involves an increase in autophagy activity or degradation of its substrates (Kroemer and Levine, 2008).

1.1.2 Modes of cell death in plants

The mode of cell death in plants is still based on cell and/or cell corpse morphology (Reape et al., 2008; Reape and McCabe, 2008; van Doorn et al., 2011; van Doorn, 2011). The term *plant apoptosis* or *apoptotic-like cell death* has been adopted for plants (Reape et al., 2008; Reape and McCabe, 2008) despite a rigid cell wall that prevents the formation of apoptotic bodies (Lam, 2004) and the lack of a specialized cell that is functionally comparable to animal phagocyte (van Doorn et al., 2011). Furthermore, plants do not have any caspase in the genome that is fundamental to the execution of animal apoptosis (Tsiatsiani et al., 2011; Van Hautegeem et al., 2015).

Van Doorn et al. (2011) have proposed the most commonly used terms describing the mode of plant cell death. First, *vacuolar cell death* or *autolytic PCD* (van Doorn, 2011) is the death that leaves an 'empty-walled cell corpse' (Figure 1.1a). Prior to an eventual death, changes in cytoskeletons occur, and cytoplasm slowly shrinks while the volume of lytic vacuole increases. The increased vacuole volume is correlated with autophagic activity (Minina et al., 2014). In the advanced stage, the tonoplast ruptures to release vacuolar content that rapidly clears the cytoplasm and organelles. This type of cell death occurs gradually (van Doorn et al., 2011) and is proposed to reflect a genetically programmed death to allow plant cells to process their own cellular corpse in a developmental PCD (Escamez and Tuominen, 2014).

The second mode of plant cell death is termed 'necrosis' or *non-autolytic PCD* (van Doorn, 2011). Opposite to vacuolar cell death, the dying of this sort

1. INTRODUCTION

1.1 Cell death as a means to flourish and survive

leaves behind an unprocessed corpse in the cell wall (Figure 1.1b). The most prominent feature preceding cell death is protoplast shrinkage without an increase in vacuolar volume. Frequently, the cell also accumulates reactive oxygen (ROS) and nitrogen (RNS) species. This mode of dying is associated with an acute response to stress, including cell death related to pathogen attack.

Whether vacuolar and necrosis cell death reflect a different underlying molecular mechanism or functional relevance is still much of a discussion (van Doorn et al., 2011; van Doorn, 2011; Reape and McCabe, 2013). For example, a mixture of processed (vacuolar cell death) and unprocessed (necrosis cell death) corpses has been reported in *Papaver* pollen self-incompatibility and victorin-induced cell death (van Doorn et al., 2011). In addition, it has been demonstrated in Norway spruce (*Picea abies*) that vacuolar cell death resulted from an undisturbed *death by autophagy* activity, and the inhibition thereof results in a *death with autophagy* that gives rise to necrosis cell corpse (Minina et al., 2013).

1.1.3 Cell death signals and executors in plants

The decision for a cell to die results from an integration of pro-death and pro-survival signals (Jones, 2001). The irreversible killing of the cell begins when it is overwhelmed with pro-death signals beyond the *point of no return* (Galluzzi et al., 2014). On a physiological level, several phytohormones can serve as a pro-death signal (Lam, 2004). Ethylene, for example, promotes senescence at plant growth completion that results in a collective cell death of an entire organ or plant (Thomas, 2013). Under pathogen attack, jasmonic acid (JA) and salicylic acid (SA) are also integrated into live-or-die decision (Lam et al., 2001).

Cell death can also be triggered on a cellular level. Jones (2001), Hatsugai and Hara-Nishimura (2010) have proposed that vacuolar maintenance and the discharge of its content precipitate cell death. Cell death is executed when tonoplast ruptures and VACUOLAR PROCESSING ENZYME (VPE), a cysteine protease, is released into the cytoplasm. In regard to vacuolar maintenance, cytoskeleton organization is also put forward as an active cell death signal (Smertenko and Franklin-Tong, 2011). Alternatively, vacuolar and plasma membrane can also fuse to release proteasomes into the extracellular space

1. INTRODUCTION

(Hatsugai et al., 2009).

Analogous to animal cell death, signals derived from mitochondria and its membrane integrity have also been proposed (Lam, 2004). The release of cytochrome *c* from mitochondria occurs prior to the plant cell death (Reape et al., 2015) and interferes with several processes including protein folding, cellular redox maintenance and ROS homeostasis (Martínez-Fábregas et al., 2014). Parallel to mitochondria, the disruption or defects in photosynthetic electron transport chain in chloroplast also changes redox and ROS homeostasis that can induce rapid cell death (Mühlenbock et al., 2008; Bruggeman et al., 2015).

Metacaspase is another group of cysteine proteases that recently emerges as functionally comparable to animal caspases (Sanmartín et al., 2005). They have been proposed to act in parallel to and with autophagy after the point of no return to execute cell death in developmental PCD (Minina et al., 2013, 2014) and in PCD after pathogen infection (Coll et al., 2014). *METACASPASE 1* and *2* (*MC1* and *MC2*, respectively) act antagonistically to promote the demise of bacterial-infected cells (Coll et al., 2010). *METACASPASE 9* (*MC9*) is implicated in the corpse clearance of treachery element (Escamez and Tuominen, 2014).

1.2 The plant immune system

Plants have evolved two coping strategies when infected with pathogens (Figure 1.2). The first line of defense involves pattern recognition receptors (PRRs), which are a group of transmembrane receptors that recognize pathogens-associated molecular pattern (PAMP). PRR recognition of PAMP activates *PAMP-triggered immunity* (PTI) (Jones and Dangl, 2006). Adapted pathogens can overcome this line of defense and invade the plant cell by unloading their virulent effectors (Coll et al., 2011), also termed *avirulence factors* or *Avr* proteins (Glazebrook et al., 1997). This activates the second type of defense called *effector-triggered immunity* (ETI) (Jones and Dangl, 2006) or *gene-for-gene resistance* (Glazebrook et al., 1997). Pathogen perception from PTI and ETI result in defense responses at the infection site and a number of cellular events, including a rapid influx of Ca^{2+} ions, transcriptional reprogramming of a defense-related genes and activation of a mitogen-activated protein kinase (MAPK) signaling cascade (Fig-

Figure 1.2: **Schematic representation of the two modes of the plant immune system** - PTI is triggered when a PRR recognizes PAMP and undergoes ligand-induced endocytosis. Adapted pathogens that can overcome this line of defense are faced with ETI. Pathogen effectors such as *Pseudomonas syringae* *AvrRpm1* and *AvrRps4* are recognized by receptor protein CC-NB-LRR and TIR-NB-LRR. The binding of effector and NB-LRR activates NDR1- or EDS1-mediated downstream responses that contribute to HR-cell death and local and systemic resistance. This figure is simplified from a model proposed by Teh and Hofius (2014).

ure 1.2; Dodds and Rathjen, 2010). In *Arabidopsis thaliana*, PTI is activated at moderately elevated (23-32°C) temperatures while ETI at relatively lower temperatures (10-23°C) (Cheng et al., 2013).

1.2.1 Plant perception of pathogenic entities

The activation of ETI requires the plant ability to distinguish between the self and non-self molecules (Coll et al., 2011). To this end, virulent effectors are

1. INTRODUCTION

sensed by nuclear-binding leucine-rich repeats (NB-LRR) receptor proteins or *R* genes (Glazebrook et al., 1997) that directly bind to virulent effectors or recognize proteins modified by pathogen effectors (Dodds and Rathjen, 2010). The recognition of compatible effectors activates signaling events that prime the plant for defense responses (Wiermer et al., 2005). Signals generated from NB-LRRs that contain a coiled-coil domain (CC) at the N-terminal are mediated by *NON RACE-SPECIFIC DISEASE RESISTANCE 1* (*NDR1*); while from NB-LRRs containing Toll-interleukin-1-receptor domain (TIR) at the N-terminal is mediated by *ENHANCED DISEASE SUSCEPTIBILITY 1* (*EDS1*) (Aarts et al., 1998). Mutant *ndr1* is susceptible to *Pseudomonas* effector proteins *avrRpt2*, *avrB*, *avrRpm1* and *avrPphB* but *eds1* only to *Pseudomonas syringae* effector protein *avrRps4* (Figure 1.2; Glazebrook et al., 1997; Parker et al., 1996).

1.2.2 Downstream responses of effector-triggered immunity

Signals from ETI can induce a more rapid, broader and stronger response to pathogen than from PTI. It modulates local resistance at the infection site as in PTI and also activates functionally overlapping SA, JA and/or ethylene signaling pathways (Dodds and Rathjen, 2010). The accumulation of SA, transcriptional reprogramming of defense-related genes and synthesis of anti-microbial compounds are essential for a broader *systemic-acquired resistance* (SAR) that affects the whole plant (Figure 1.2; Glazebrook et al., 1997; Coll et al., 2010). Pathogen-induced SA requires a functional *SALICYLIC ACID INDUCTION DEFICIENT 2* (*SID2*) that converts SA precursor, chorismate into isochlorismate (Wildermuth et al., 2001) in chloroplast (Serrano et al., 2013). SA transport into cytosol is mediated by *ENHANCED DISEASE SUSCEPTIBILITY 5* (*EDS5*) (Serrano et al., 2013), which partially contributes to SAR (Nawrath et al., 2002). SAR activation is correlated with the expression of *PATHOGENESIS-RELATED GENE 1, 2, 5* (*PR1*, *PR2* and *PR5*, respectively) (Glazebrook et al., 1997). SA-dependent SAR induction and the expression of *PR1*, *PR2* and *PR5* genes are under the control of *NON-EXPRESSOR OF PR GENES 1* (*NPR1*) (Cao et al., 1994).

1.2.3 Hypersensitive response

Hypersensitive response (HR) is a form of rapid cell death occurs after plant-microbe interaction (Greenberg, 1996). It is intertwined with, but not equal to ETI and/or SAR (Wiermer et al., 2005; Coll et al., 2011). HR-cell death occurs at the initial infection site and then propagates to the neighboring cells to a certain degree (Greenberg, 1996). It is thought to be invoked only when the defense signal has crossed a certain cellular threshold (Lam et al., 2001; Jones and Dangl, 2006). On a microscopic level, it displays necrosis death mode with some additional features (van Doorn, 2011) such as cell wall thickening and organelle swelling (Dickman and de Figueiredo, 2011).

1.2.3.1 Lesion mimic mutant as a tool to unravel HR

Lesion mimic mutants (LMM) are mutants that display HR-cell death phenotype. LMMs can be classified into *initiation* mutants that spontaneously initiate cell death, or *propagation* mutants that fail to confine death in a local area (Lorrain et al., 2003) - a phenotype that is also referred as '*runaway cell death*' (Jabs et al., 1996; Brodersen et al., 2002). The majority of LMMs display an autoimmune phenotype, in which cell death is accompanied by constitutive expression of pathogen-associated markers (Lorrain et al., 2003; Palma et al., 2010). Identification and characterization of LMMs have untangled the molecular events leading up to HR (Lorrain et al., 2003; Coll et al., 2011). Oxidative stress related to photosynthesis or chloroplast maintenance, influx of ions or ROS and modulation of stress-related gene expression are major mechanisms identified that are directly involved in ETI processes. Another set of mechanisms identified are fatty acids homeostasis and intracellular trafficking (Bruggeman et al., 2015). For instance, the characterization of a LMM *accelerated cell death 11* (*acd11*) reveals that it is involved in regulating phytoceramide level in *Arabidopsis* (Brodersen et al., 2002; Simanshu et al., 2014). The loss of *syntaxin of plants 121* and *122* (*syp121 syp122*) result in a LMM phenotype. Both *syp121* and *syp122* are coat proteins that function in vesicular trafficking in the endomembrane system (Zhang et al., 2008).

1. INTRODUCTION

1.3 Protein trafficking in the endomembrane system

The endomembrane system is composed of all single membrane-delimited organelles that are connected through a constant donating and receiving of vesicles (Figure 1.3). In the secretory pathway, vesicles containing newly synthesized proteins travel from endoplasmic reticulum (ER), trans-Golgi network (TGN) then plasma membrane or vacuole or lysosome. Conversely, transmembrane proteins or extracellular molecules are endocytosed from the plasma membrane and passed onto endosomes for delivery to vacuole (Bassham et al., 2008).

Figure 1.3: **Schematic representation of the protein trafficking in the endomembrane system** - Each organelle in the endomembrane system is connected through a constant donating and receiving of vesicles that are coated with proteins to mediate efficient trafficking. Sorting of endosomal cargo back to TGN requires retromer complex. The ESCRT-complex mediates the sorting of transmembrane proteins into the ILV of a late endosome, giving rise to MVBs that are delivered to vacuole/lysosome for degradation. This figure is modified from Herberth (2012).

1.3 Protein trafficking in the endomembrane system

Efficient vesicle trafficking relies on a distinctive assemblage of coat proteins on the donor compartment and receptor proteins on the membrane of the receiving organelle (Figure 1.3). For example, the sorting of vacuolar cargo receptor from endosomal compartment back to TGN requires the formation of a *retromer* complex; while the sorting of transmembrane proteins into intraluminal vesicles (ILV) of an endosome is mediated by the Endosomal Sorting Complex Required for Transport (ESCRT) (Schellmann and Pimpl, 2009). At the cargo's destination, cargo and organelle membrane fuse to release the cargo content. This fusion is facilitated by Soluble N-ethylmaleimide-sensitive factor Attachment protein REceptor (SNARE) proteins on the vesicles and a group of SNARE proteins called *syntaxins* on the membrane of targeted organelle (Bassham et al., 2008).

1.3.1 The ESCRT-complex

The ESCRT-complex recognizes and sorts of mono-ubiquitinated or lysin-63-linked polyubiquitinated transmembrane proteins into the ILV of a late endosome, giving rise to a specialized form called multivesicular bodies (MVBs) (Bache et al., 2003b; Babst, 2005). MVBs then travel to vacuole to unload their content for degradation (Katzmann et al., 2001).

1.3.2 The ESCRT-complex machinery

The ESCRT-complex is first identified in budding yeast (*Saccharomyces cerevisiae*) and is made up of four heteromeric complexes named ESCRT 0-III. They interact sequentially to recognize and incorporate its target into an ILV of an MVB (Figure 1.4; Katzmann et al., 2001; Babst et al., 2002a,b). ESCRT-0 initiates the machinery by one of its components, Vacuolar sorting protein27p (Vps27p). Vps27p recognizes its ubiquitinated target (Bache et al., 2003b) and enlists the ESCRT-I complex to the endosome (Raiborg et al., 2001; Bache et al., 2003a) by binding to one of ESCRT-I components, Vps23p (Figure 1.4a; Katzmann et al., 2001, 2003). ESCRT-I further recruits ESCRT-II and creates a cargo-enriched region that initiates membrane invagination (Figure 1.4b). ESCRT-II initiates ESCRT-III formation that in turn facilitates ILV formation and scission

1. INTRODUCTION

Figure 1.4: **Schematic representation of the ESCRT-complex machinery** - The ESCRT-complex interacts sequentially to form MVB.

- a)** ESCRT-0 initiates the machinery by recognizing ubiquitinated target. ESCRT-0 recruits the ESCRT-I that in turn enlists the ESCRT-II components.
- b)** ESCRT-I and ESCRT-II create a cargo-enriched region that facilitates membrane invagination and recruit ESCRT-III complex.
- c)** ESCRT-III and its accessory subunits remove ubiquitin from cargo and enclose ILV, forming a mature MVB.

The figure is recreated and adapted from Herberth (2012).

by recruiting *accessory ESCRT-III subunits* (Figure 1.4c; Babst et al., 2002a; Babst, 2005). Accessory ESCRT-III subunits, Bro1p recruits Doa4p to remove ubiquitin from the cargo before incorporating into the ILV (Babst et al., 2002b). After cargo has budded off into the MVB, Vps4p interacts with Vps20-associated 1p (Vta1) to dissociate the ESCRT-complex from the MVB membrane for the next sorting event (Babst et al., 1998; Babst, 2005).

In the *Arabidopsis* genome, most of the ESCRT-complex components and its accessory ESCRT-III subunits exist, except for the ESCRT-0 components (Winter and Hauser, 2006). They interact in a similar manner as in the yeast and mammalian system (Shahriari, 2008; Shahriari et al., 2011). For ESCRT-I components, two additional homologues of Vps23p (called *VPS23.1/ELCH*), *VPS23.2* and *VPS23.3* were found as well as another homologue of Vps28p (*VPS28.1* and *VPS28.2*) and Vps37p (*VPS37.1* and *VPS37.2*) (Shahriari, 2008). Additionally, two plant-specific ESCRT components were identified: FYVE

1.3 Protein trafficking in the endomembrane system

DOMAIN PROTEIN REQUIRED FOR ENDOSOMAL SORTING 1 (FREE1) as a part of ESCRT-I complex (Gao et al., 2014) and POSITIVE REGULATOR OF SKD1 (PRO1) as an interactor of Vps4p and Vta1p plant counterparts, SUPPRESSOR OF K⁺ TRANSPORT GROWTH DEFECT 1 (SKD1) and LYST-INTERACTING PROTEIN 5 (LIP5), respectively (Reyes et al., 2014).

1.3.3 Consequences of a dysfunctional ESCRT-complex

In yeast, the components of the ESCRT-complex are among the *Class E vacuolar protein sorting (vps)* genes. Yeast lacking these *vps* genes display an accumulation of endosomes seen as a distinctive enlarged late endosome or *prevacuolar compartment (PVC)* that are referred as *class E compartment* (Raymond et al., 1992). Class E compartment reflects the failure to sort cargoes into the ILV of the MVB, which disturbs MVB maturation and its delivery to vacuole (Babst, 2005). In plants, the appearance of class E compartment was reported when the dominant negative version of SKD1 was expressed in tobacco, *Arabidopsis* cultured (Haas et al., 2007) and trichome cells (Shahriari et al., 2011), and in mutant plant lacking the Doa4p plant counterpart, *apoptosis-linked gene 2 interacting protein-x (alix)* (Kalinowska et al., 2015).

The absence of a functional ESCRT-component affects MVB maturation that also disturbs other biological processes. In most cases, the disturbance is a consequence of an endocytic down-regulation of transmembrane signaling receptors (Saksena and Emr, 2009). For example, *Arabidopsis* double mutant of ESCRT-III components, *charged multivesicular body protein 1a and b (chmp1a and chmp1b)*, respectively) displays a defective bilateral symmetry and polar differentiation due to the failure to sort auxin transporters, PINFORMED 1 and 2 (PIN1 and PIN2, respectively) and AUXIN-RESISTANT1 (AUX1) into the ILV of the MVB (Spitzer et al., 2009). The ESCRT-I mutant, *vps37.1* and *vps28.2* are impaired in PTI due to a decrease in the endocytosis of a PRR, FLAG-ELLIN SENSING 2 (FLS2) that perceives the bacterial PAMP, flagellin 22 (flg22) (Spallek et al., 2013).

Another disturbed process reported is the mutant of Vps23p plant counterpart, *elch*. It displays a unique cluster-like trichome phenotype in 2% of the

1. INTRODUCTION

Figure 1.5: **Representatives of wild-type and *elch* trichome** as seen in *elch*. Scale bar: 200 μ m.

trichomes. This cluster-like *elch*-trichome is an appearance of two trichomes stemming from a single pavement cell (Figure 1.5) that reflects a defect in cytokinesis (Spitzer et al., 2006). The *elch*-trichome phenotype is enhanced in the double and triple mutant of *elch* and other ESCRT-I mutants: *elch vps28.1*, *elch vps28.2*, *elch vps37.1*, *elch vps37.2* and *elch vps28.2 vps37.1* (Keshavaiah, 2008).

1.3.3.1 The ESCRT-complx and cell death

Mutants of most of the ESCRT-components in animal cells develop a '*cell-autonomous death through apoptosis*' phenotype, i.e. they die by apoptosis without any external stimulus (Wegner et al., 2011). This phenomenon was first described in mice lacking the mammalian Vps27p counterpart, HEPATOCYTE GROWTH FACTOR-REGULATED TYROSINE KINASE SUBSTRATE (HRS). Endodermal cells of these mice undergo non-programmed apoptosis causing mislocalized and misformed embryo (Komada and Soriano, 1999). Another example is the mammalian ALIX. It interacts with mammalian Vps23p/ELCH, ESCRT-III complex (Mahul-Mellier et al., 2006) and APOPTOSIS-LINKED GENE2 (ALG2) in a Ca²⁺-dependent manner (Missotten et al., 1999) to initiate the caspase activity that executes neuronal cell death (Mahul-Mellier et al., 2009).

In *Arabidopsis*, ALIX also interacts with the same components - ELCH and ALG2 (Personal communication S Schellmann, L Kruppe) - and ALIX reduction results in lethality during vegetative growth (Kalinowska et al., 2015). Additionally, the lack of a functional SKD1 (Cai et al., 2014) and the over expression of dominant-negative SKD1 in trichome cells (Shahriari, 2008; Shahriari et al., 2010b) cause the cells to die from vacuole loss or fragmentation.

1.4 An ESCRT-I interactor, CFS1 displays a lesion-mimic phenotype

Another functional link between the ESCRT-complex and cell death in plants came from a phenotypic screening of an ESCRT-I interactor mutant, *cell death-related fyve, sylf domain-containing 1 (cfs1)* that displays a runaway, lesion-mimic phenotype in both null (*cfs1-1* and *cfs1-2*) and non-null alleles (*cfs1-3*) (Sutipatanasomboon, 2012). CFS1 came up as FYVE2 from a bioinformatic screen for a Vps27p functional equivalence, along with another plant-specific proteins containing a Fab1, YOTB, Vac1 and EEA1 (FYVE) domain, FYVE1 (named CFS2 in this study) (Shahriari, 2008). Protein sequence revealed that FYVE1 and FYVE2 are homologous (Figure 1.6; Herberth 2012) and conserved throughout the plant kingdom (Herberth 2012; Personal communication B Marin).

Figure 1.6: **Domain structure of CFS1 and CFS2** -CFS1 is homologous to another plant-specific protein CFS2. Both contain a FYVE domain at the N-terminal and a SYLF domain at the C-terminal. Only CFS1 has a PSAPP-motif that facilitates its interaction with ELCH. This figure is modified from Herberth, 2012

Both CFS1/FYVE2 and CFS2/FYVE1 possess a domain of an unknown function 500 (DUF500) (Figure 1.6; Herberth, 2012) that is homologous to an actin binding domain, Ysc84 actin binding (YAB) in yeast (Robertson et al., 2009; Herberth, 2012) and a phosphatidylinositol (3,4,5)-trisphosphate (PI(3,4,5)P(3)) binding domain named SH3YL1, Ysc84p/Lsb4p, Lsb3p, plant FYVE proteins (SYLF) in mammals (Hasegawa et al., 2011). Only CFS1 contains a PSAP-motif in the N-terminal that binds to ELCH and VPS23.2 (Shahriari, 2008; Herberth, 2012).

Biochemical characterization of FYVE2 revealed that its DUF500 domain binds to actin and phosphatidylinositol 3-phosphate (PI3P). This binding is

1. INTRODUCTION

instrumental in the protein localization on late endosomes (Herberth, 2012). However, the lack of ubiquitin-binding property (Herberth, 2012) and FYVE2 influence on ELCH localization (Sutipatanasomboon, 2012) negate the hypothesis that FYVE2 acts as a plant Vps27p. Taken the biochemical findings and the mutant phenotype into consideration, *FYVE2* is therefore renamed to *CFS1*.

1.5 Aims of this study

Screening in Yeast-2-Hybrid and bimolecular fluorescence complementation have revealed *CFS1* interactions with proteins involved in heat stress response such as CARBOXYL TERMINUS OF HSC70 INTERACTING PROTEIN (CHIP) and biotic stress response such as BINDING PARTNER OF ACD11 1 (BPA1) (Ulbricht, 2011). BPA1 binds to another lesion-mimic protein, ACD11 (Brodersen et al., 2002; Petersen et al., 2009). Mutant *acd11* displays an autoimmune phenotype, i.e. a runaway cell death phenotype without any pathogen perception and constitutive activation of a defense response (Brodersen et al., 2002; Palma et al., 2010). The phenotypic resemblance of *cfs1* and *acd11* phenotype, together with *CFS1* protein interaction network suggest its involvement in HR-cell death and implies a connection between the ESCRT-complex and immunity-related cell death (Sutipatanasomboon, 2012).

To provide a framework on how the ESCRT-complex factors in the plant HR-cell death, this study is aimed to unravel the role *CFS1* plays in plant cell death. To this end, the cell death phenotype in *cfs1* is characterized to investigate *CFS1* involvement in HR and the effect of its absence to ESCRT-complex protein trafficking.

2. Materials and Methods

2.1 Molecular cloning

For the purpose of plasmid amplification, *Escherichia coli* (*E. coli*) strain DH5 α was employed. *E. coli* strain DB3.1 was used to amplify vectors containing *ccdB* operon. All *Agrobacterium tumefaciens* used in this study was of the strain GV3101 containing binary Ti plasmid pMP90RK (pTiC58 Δ T-DNA). The chromosomal background was resistant to 25 μ M rifampicin; the binary Ti plasmid was resistant to 25 μ M gentamicin and 25-50 μ M kanamycin.

2.1.1 Cloning of *CFS1* promoter and genomic region

Genomic sequence of *CFS1* (AT3G43230) and its upstream region were retrieved from Seqviewer of The Arabidopsis Information Resource (November 2012 Release). Several oligonucleotides (Sigma-Aldrich) were designed to cover from 4.862kilobases (kb) upstream of *CFS1* until 0.380kb downstream of translation termination codon, 0.052kb of which was annotated as a part a 5'-untranslated region (UTR) of the next gene (AT3G43240) (Figure2.1, Table 2.1). The AscI and XhoI restriction sites were introduced to the 5'-end of primer ASU59 and ASU207 to facilitate subcloning (Figure 2.1).

Genomic DNA of *Arabidopsis thaliana* ecotype Columbia-0 (Col-0) was used as a template for polymerase chain reactions (PCR)-amplification. The region was split into three fragments, and each fragment was PCR-amplified in a 25 μ L reaction (1xHF-buffer, 0.5 μ M dideoxynucleotides (dNTPs), 1pmole forward and reverse primers each, 0.4U of High-Fidelity DNA Polymerases (Fermentas)) using the following condition: 2mins of initial denaturation at 98 $^{\circ}$ C followed by 35 cycles of denaturation step at 98 $^{\circ}$ C for 45sec, annealing at 55 $^{\circ}$ C for 45sec and extension at 72 $^{\circ}$ C for 1.5min, then final extension at 72 $^{\circ}$ C for 5 minutes. PCR products were purified by column from GeneJET PCR purification kit (Fermentas) and ligated to pJET1.2 cloning vector from CloneJET

2. MATERIALS AND METHODS

Figure 2.1: **Schematic representation of *AT3G43230* in the genome - *CFS1* genomic region (*gCFS1*) and the upstream region considered as a promoter region (*pCFS1*).** Primer sequences is listed in Table 2.1

Table 2.1: List of primers used in cloning of *CFS1* promoter and genomic region

Primer ID	Description	Primer
ASU59	3'UTR of AT3G43220 with AscI	GGCGCGCCaaaacgaagctcgatttca
ASU60	5'UTR of CFS1 with XhoI	CTCGAGcgatttatgggattgaagaa
ASU61	Promoter second fragment fwd	cataaggaaagtccaaagca
ASU62	Promoter second fragment rev	aagcaaatcaagatttgaggat
ASU64	5'UTR of AT3G43240	cttggaaccaaagattgat
ASU65	Promoter third fragment fwd	aaagatagaccgcatgaaaa

ASU207	UTR CFS1 before ATG fwd with XhoI	CTCGAGgccttaaaaaatgaaacttac

Non-native sequences are written in capital letters.

PCR Cloning kit (Fermentas) following the manufacturer's protocols. Plasmid DNA from ligation-positive transformant was sequenced in a 10 μ L reaction using BigDye[®] Terminator v3.1 Cycle Sequencing Kit (Applied Biosystems) with either 2.5 μ M pJET1.2 forward or reverse primer using the following condition: 2min of denaturation at 96°C followed by 35 cycles of denaturation at 96°C for 10sec, annealing at 55°C for 5sec and extension at 60°C for 4min. Capillary electrophoresis was performed by Cologne Center for Genomics. Obtained chromatograms were visualized and corrected using FinchTV (Geospiza) and sequences were aligned to template using CLC Main Workbench 7 (QIAGEN Aarhus A/S).

The first two fragments that contain the promoter region were fused via BamHI in *CFS1* sequence and XhoI site. The fused fragments were subcloned to pAMPAT:2x35s::GUS, via its AscI and XhoI site to generate pCFS1::GUS. GUS in pCFS1::GUS was replaced by gCFS1 via ApaI site in pCFS1 and NotI site in pAMPAT.

2.1.2 Construction of genes tagged with fluorescent protein

Construction of a gene of interest tagged with a fluorescent protein was done using GATEWAY[®] recombination technology (Invitrogen) that enables the transfer of a specific DNA fragment to a binary vector using homologous recombination instead of ligation. By flanking the fragment with a specific attachment (*att*) site, the reading frame of the gene is maintained throughout the process.

First, the DNA sequence of interest is flanked by *attB*₁ and *attB*₂ sites from amplification with gene-specific primers. The obtained PCR product is incorporated to a donor vector via BP reaction. A donor vector contains an *attP*₁ and *attP*₂ site flanking the lethal *ccdB* gene that is disrupted after homologous recombination at the *attP*₁ and *attP*₂ sites. Successful recombination of DNA sequence into the donor vector is termed entry clone and is selected by the growth of *E.coli* DH5 α on selection medium and subsequent restriction digestion of plasmid DNA, positive clones were chosen. Plasmid DNA from entry clones is sequenced to confirm the integrity of amplified sequence as described in the previous section. Finally, LR reaction is performed to transfer the DNA

2. MATERIALS AND METHODS

Table 2.2: List of vectors and their features

Vector name	Features	Plasmid selection (μM)
Cloning vectors		
pDONR201 (Invitrogen)	Contains attP-sites flanking <i>ccdB</i> operon	Kanamycin 25-50
pDONR207 (Invitrogen)	Contains attP-sites flanking <i>ccdB</i> operon	Gentamicin 25
pJET1.2 (Fermentas)	Contains multiple cloning sites in the <i>eco47IR</i> gene that is lethal to <i>E.coli</i> when expressed	Ampicilin 100 or Carbenicillin 50
Binary vectors		
pAMARENA-mCherry (Marc Jakoby)	Contains 2 cauliflower mosaic virus 35s RNA (2x35s) promoter, mCherry and Strep tag at the N-terminal of the attL-site flanking the <i>ccdB</i> gene and <i>BAR</i> gene cassette, encoding glufosinate resistance in plants	Ampicilin 100 or Carbenicillin 50
pAMPAT (GenBank: AY436765.1)	Contains 2x35s and attL-sites flanking the <i>ccdB</i> gene and <i>BAR</i> gene cassette, encoding glufosinate resistance in plants	Ampicilin 100 or Carbenicillin 50
pBatTL-eGFP (Joachim Uhrig)	Contains 35s promoter, eGFP tag at the C-terminal of the attL-site flanking the <i>ccdB</i> gene and <i>BAR</i> gene cassette, encoding glufosinate resistance in plants	Spectinomycin 50
pCFS1	Originated from pAMPAT but contains instead <i>CFS1</i> promoter region	Ampicilin 100 or Carbenicillin 50
pEarleyGate104 (Earley et al., 2006)	Contains 35s promoter, YFP tag at the N-terminal of the attL-site flanking the <i>ccdB</i> gene and <i>BAR</i> gene cassette, encoding glufosinate resistance in plants	Kanamycin 25-50
pENSG-YFP (Feys et al., 2005)	Destination vector containing 2x35s promoter, YFP tag at the N-terminal of the attL-site flanking the <i>ccdB</i> gene and <i>BAR</i> gene cassette, encoding glufosinate resistance in plants	Ampicilin 100 or Carbenicillin 50

fragment to a destination vector, a binary vector containing a promoter, *attL*₁ and *attL*₂ sites and the fluorescent tag such as enhance green fluorescent protein (eGFP), yellow fluorescent protein (YFP) or mCherry. Successful recombination is selected by the growth of *E.coli* DH5 α on selection medium, followed by restriction digestion of plasmid DNA.

All donor and destination vectors used in this study are listed in Table 2.2. Entry and expression clones used in this study are listed in Table 2.3.

Table 2.3: List of constructs used in this study

Construct name	AGI code	Vector
mCherry-ARA7	AT4G19640	pAMARENA (Herberth, 2012)
YFP-ATG8a	AT4G21980	pENSG-YFP (Alexandra Steffens)
pCFS1-gCFS1	AT3G43230	pCFS1
CFS1 +stop		pDONR201 (Herberth, 2012)
GUS		pAMPAT
pCFS1:GUS		pCFS1
ELCH +stop	AT3G12400	pDONR201 (Spitzer et al., 2006)
YFP-ELCH		pEarleyGate104
SYP61 +stop	AT1G28490	pDONR207 (Florian Hessner)
mCherry-SYP61		pAMARENA
mCherry-VTI12	AT1G28490	pAMARENA (Marc Jakoby)

2.1.3 Transformation into host and plasmid DNA preparation

2.1.3.1 Transformation into *E.coli*

Desired constructs were introduced to *E. coli* DH5 α or DB3.1 cells by heat shock transformation as follows: 50 μ L of competent cells were incubated with the construct at 42°C for 2 minutes, then 350 μ L of iced-cold liquid LB medium were immediately added to the cells then cultured at 37°C. After incubation for at least 30 minutes, the culture was spread on 1.5% agar- LB medium with the corresponding antibiotics listed in Table 2.2 and grown overnight at 37°C.

2. MATERIALS AND METHODS

2.1.3.2 Transformation into *Agrobacterium*

The construct was mixed with iced-cold chemically competent *Agrobacterium* and heat shock at 42°C for 2min, then 350µL iced-cold liquid YEB medium was immediately added to the cells and cultured at 28°C for two hours. One third of the culture was selected at 28°C for 48 - 72 hours on 1.5% agar-YEB medium containing the respective antibiotics listed in Table 2.2.

Plasmid DNA from transformed *E. coli* and *A. tumefaciens* were prepared by using the spin column-based GeneJET Plasmid Miniprep Kit (Fermentas). In case of *A. tumefaciens*, purified plasmid was introduced to *E. coli* DH5α as described, and the plasmid DNA obtained from *E. coli* was used for selection by restriction digestion.

2.2 Mutants and transgenic lines

All mutants used in this study, their corresponding locus, ecotype background and molecular markers are listed in Table 2.4. Mutant *cfs1-1*, *cfs1-2* and *cfs1-3* are *Agrobacterium* transferred DNA (T-DNA) insertion lines (Alonso et al., 2003) and were obtained from The Nottingham Arabidopsis Stock Centre. Britta Müller provided seeds of *elch*, *vps28.2*, *vps37.1* and *elch vps28.2 vps37.1 (i³)*. Ethyl methanesulfonate (EMS)-mutagenized *esd1-2*, *eds5-1* and *sid2-1* were from Jane Parker (Max Planck Institute for Plant Breeding Research Cologne). John Mundy (University of Copenhagen) provided the *laz1-5* T-DNA insertion line (Malinovsky et al., 2010).

Stable transgenic plants used in this study were in Col-0 ecotype background and are listed in Table 2.5. Plants expressing bacterial enzyme naphthalene hydroxylase G (*nahG*) were obtained from John Mundy (University of Copenhagen) and Lifeact-eGFP (Riedl et al., 2008) from Alexandra Steffens (Steffens et al., 2014). Other transgenic lines were generated by *Agrobacterium*-mediated transformation using floral-dip method (Clough and Bent, 1998) or crossing to an existing transgenic line.

2.2 Mutants and transgenic lines

Table 2.4: List of mutants used in this study and the corresponding locus, ecotype background and molecular marker

Mutant name	Locus	Ecotype	Molecular markers
<i>cfsl-1</i> (SALK_018265)	AT3G43230	Col-0	wild-type mutant PCR: primers ASU79 and ASU80 PCR: primers ASU80 and ASU9
<i>cfsl-2</i> (SALK_024058)	AT3G43230	Col-0	wild-type mutant PCR primers, ASU49 and ASU50 PCR: primers ASU49 and ASU9

^t generated by Agrobacterium-mediated transformation

^c generated by crossing to an existing transgenic line

2.2.1 Crossing

Crossing was done by emasculating flowers of *cfs1* plants under a stereo microscope with a fine tweezer, and subsequent pollination was within 12-42 hours. F1 progeny were selected by the detection of a fluorescent signal or by resistance to glufosinate. Positive transformants were pooled for F2 seeds. Homozygous plants were selected in F2 generation as listed in Table 2.4, and phenotypic analysis was performed in F3. In case of dominant marker as in *nahG*, progeny of at eight F2 individuals were selected in the F3 generation.

2.2.2 Floral dip

Single transformed *Agrobacterium* clone was selected and cultured in 250mL YEB medium supplemented with antibiotics at 28°C for 48 - 72hours. Immature young flower buds of plants were dipped in overnight culture containing 5%(w/v) sucrose and 0.05%(v/v) of surfactant Silwet L-77 (Clough and Bent, 1998). Transformed plants were placed horizontally in darkness for 12-24 hours before transferring to the greenhouse. Transformed plants were selected

in T1 generation after cotyledons were fully opened for glufosinate resistance by spraying with 0.01%(v/v) Basta solution (Aventis) containing 0.001%(v/v) Tween-20.

2.2.3 Selection with molecular markers

PCR-amplification or Cleaved Amplified Polymorphic Sequences (CAPS) was employed for selection of individuals having homozygous loci (Table 2.4). All primers were designed using the Primer3 software (Untergasser et al., 2012). Their sequences are listed in Table 2.6.

2.2.3.1 DNA extraction

DNA for genotype determination was extracted from a 1-2cm leaf disc. The disc was crushed in a 2mL microcentrifuge tube using a QIAGEN Tissue Lyser for 1.5 minutes at 30Hz. Ground samples were briefly centrifuged, and 125 μ L of extraction buffer (25mM NaCl, 20mM Tris/HCl (pH = 8.0), 25mM ethylenediaminetetraacetic acid (EDTA) (pH = 8), 0.5%(v/v) sodium dodecyl sulfate (SDS)) was added to the sample. The tube was inverted several times and 36.5 μ L of 3M sodium acetate (pH = 5.5) was added and centrifuged at maximum speed for 2 minutes. Supernatant was transferred to a new microcentrifuge tube, mixed with 125 μ L isopropanol and centrifuged for 10 minutes at maximum speed. Supernatant was gently removed, and pellet was wash with 500 μ L absolute ethanol then centrifuged for 2 minutes at maximum speed twice. Supernatant was removed and air-dried and resuspended in 50 μ L sterile water.

2.2.3.2 PCR-amplification and CAPS

To determine the genotype of an individual with PCR, a 20 μ L PCR reaction was performed using DreamTaq[™] Green PCR master mix (Fermentas) with 1pmole of each forward and reverse primer. The PCR condition was as follows: 2 minutes of initial denaturation at 94°C, followed by 35 cycles of denaturation at 94°C for 45 seconds, annealing for 45 seconds at the temperature indicated in Table 2.6, extension at 72°C for 1.5 minutes. Final extension was performed at 72°C for 5 minutes. The PCR products were separated and visualized in 1%(w/v) agarose gel electrophoresis stained with 0.1%(v/v) 10 mg/ml ethidium bromide.

For CAPS, the same PCR condition was used, but the reaction performed contained 1xDreamTaq[™] PCR buffer, 1pmole of each forward and reverse primer, 1 μ M dNTPs and one unit of DreamTaq[™] DNA polymerase (Fermentas). Afterwards, 10 μ L of PCR product was digested with 5 unit of restriction enzyme (Fermentas) as listed in Table 2.4. Digested product was separated and visualized in 2%(w/v) agarose gel electrophoresis stained with 0.1%(v/v) 10 mg/ml ethidium bromide.

2.2.4 Biolistic transformation

Biolistic transformation was employed to transiently express a gene of interest tagged with fluorescent protein in epidermal leaf cells. Coated particles were prepared as described in Mathur et al. (2003) with some modifications. For each transformation, approximately 1200ng of DNA was coated to 60mg of gold particles. 20 μ L of 2.5M CaCl₂ and 8 μ L of 0.1M spermidine were added to the coated gold particles. The mixture was filled up to 50 μ L by sterile water and vortexed for 10min. Coated particles were pelleted by centrifugation at 10,000rpm for 5sec. Supernatant was discarded by pipetting, and pellet was washed with 100 μ L 70%(v/v) ethanol, centrifuged and washed again with 40 μ L of absolute ethanol. Coat particles were then resuspend in 12 μ L absolute ethanol, spotted on a macrocarrier and air-dried. Each construct was bombarded to several epidermal cells using biolistic PDS-1000 He System (Bio-rad) with the following parameters: 900psi rupture disc pressure, 26-inch Hg

2. MATERIALS AND METHODS

vacuum. After transformation, samples were incubated for 14-16 hours in the dark before observation.

2.3 Plant growth condition

Seeds were sown on 0.8%(w/v) agar half strength Murashige and Skoog basal (MS) medium (Duchefa Biochemie bv) or on soil, stratified at 4°C for 1-3 days and grown in greenhouse or growth chamber under long day condition (16 hours light, 8 hours dark) at 22°C, approximately 60% relative humidity, 150-300nmol light intensity. At elevated temperature, plants were grown in growth cabinet (SANYO versatile environmental test chamber, MLR-350) at 28°C under the same conditions as in growth chamber.

2.3.1 Surface sterilization

Seeds were sterilized by gently shaking in 70% ethanol for 5 minutes, followed by bleach solution (4%(v/v) sodium hypochlorite, 0.1%(v/v) Triton™-X100) for 15 minutes. Seeds were washed at least three times with sterile water, suspended in 0.15% plant agar solution and plated on medium.

Alternatively, vapor-phase seeds sterilization was adopted by placing seeds in a desiccator next to chlorine gas. The gas was generated by mixing hydrochloric acid to 10% sodium hypochlorite solution (Carl-Roth) in 3:100 ratio.

2.3.2 Induction of nutrients starvation condition

To simulate nutrient starvation condition, components of MS medium were prepared as five separate stocks as listed in Table 2.7. Nitrogen source was removed from medium by replacing NH_4NO_3 and KNO_3 in stock A1 with equal mole of KCl . Seedlings were first germinated on 0.8%(w/v) agar MS medium prepared from stock A1, A2, B, C and D as described in Table 2.7. 7-10 day-old seedlings were transferred to either complete darkness or to MS medium lacking nitrogen supplemented with 1%(w/v) sucrose and grown for 10 days.

2.3 Plant growth condition

Table 2.7: Components of MS medium stock solutions

Component	Stock concentration	Working concentration
STOCK A1 (100x SALTS)		
NH_4NO_3	411.6 mmol	20.88 mmol
KNO_3	375.2 mmol	18.76 mmol
$CaCl_2 \cdot 2H_2O$	59.8 mmol	2.99mmol
KH_2PO_4	24.95 mmol	1.25 mmol
H_3BO_3	2.007 mmol	0.1 mmol
$MnSO_4 \cdot H_2O$	2.08 mmol	0.104 mmol
$ZnSO_4 \cdot 7H_2O$	0.6 mmol	0.03 mmol
KI	0.1 mmol	0.00498 mmol
$Na_2MoO_4 \cdot 2H_2O$	0.021 mmol	0.001037 mmol
STOCK A2 (100x)		
$CuSO_4 \cdot 5H_2O$	40 μ mol	0.1 μ mol
$CoCl_2 \cdot 6H_2O$	42 μ mol	0.105 μ mol
STOCK B (100x)		
$MgSO_4 \cdot 7H_2O$	15 mmol	1.498 mmol
STOCK C (200x)		
$Fe \cdot Na - EDTA$	1.998 mmol	0.0999 mmol
STOCK D (10000x)		
Thiamine hydrochloride	29.65 μ mol	0.3 μ mol
Glycine	2704 μ mol	27.04 μ mol
Nicotinic acid	406.154 μ mol	4.074 μ mol
Pyridoxine HCl	243.1434 μ mol	2.439 μ mol

Full-strength MS-medium is prepared by combining stock A1, A2, B, C and D then 0.56mmol myo-inositol is added. Medium is adjusted to pH = 5.8 with KOH

2. MATERIALS AND METHODS

2.4 Real-time quantitative reverse transcription PCR

2.4.1 RNA preparation

Leaf 1 and 2 from five 28-30 days-old plants after germination were collected, pooled and frozen in liquid nitrogen. Samples were ground in liquid nitrogen using a mortar. Total RNA was extracted using RNeasy™ Plant Mini kit (QIAGEN) following the manufacturer's protocol. DNase digestion was performed with extracted total RNA using 1 unit of DNaseI (Fermentas) at 37°C for 30 minutes. DNaseI was inactivated by adding 2mM EDTA and incubated at 65°C for 10 minutes. The integrity of extracted RNA was tested by separation in 1.5 %(w/v) formaldehyde agarose gel stained with 0.1 %(v/v) 10 mg/ml ethidium bromide solution. The quantity of extracted RNA was determined by GE NanoVue Spectrophotometer.

2.4.2 First strand cDNA synthesis and RT-qPCR

After quantification, equal amount of total RNA were reverse-transcribed with an oligo(dT) primer and SuperScript™ III reverse transcriptase (Invitrogen) following the manufacturer's instructions. Subsequent quantitative real-time PCR was performed with Power SYBR Green PCR Master Mix (Applied Biosystems) in an Applied Biosystems 7300 Real-Time PCR System. All reactions were performed in 10µL reaction using a two-step protocol as follows: initiation at 50°C for 2 minutes, 95°C for 10 minutes, 40 cycles of 95°C for 15 seconds, 60 °C for 1 minute, followed by a dissociation step at 95°C for 15 seconds, 60°C for 20 seconds then then 95°C for 15 seconds, 60°C for 15 seconds. Gene-specific primers used are listed in Table 2.8.

All data were from three biological replicates with two to three technical replicates each. Fold change in expression was calculated using $2^{\Delta\Delta C_T}$ method (Livak and Schmittgen, 2001) with *ELONGATION FACTOR-1ALPHA* (*EF1 α*) as an endogenous control (Czechowski et al., 2005). Normality test was performed using Shapiro-Wilk normality test, and difference between groups were tested by the analysis of variance (ANOVA) or Kruskal-Wallis rank sum.

2.5 Histology and microscopy

2.5.1 Trypan blue staining

The degree of dead cells in the leaf was quantify by area of cells positivly stained by trypan blue. Staining procedure were performed with some modification from Bowling et al. (1997). Leaves were detached and submerged in 70°C trypan blue staining solution (2.5mg/ml trypan blue, 25%(w/v) lactic acid, 23%(v/v), saturated phenol, 25%(v/v) glycerol). The staining solution were vacuum infiltrated for 5 minutes and boiled for 2 minutes. Specimens were removed after solution has cooled and destained several times in 2.5g/mL chloral hydrate until cleared and equilibrated in 70%(v/v) glycerol. Images of stained samples were taken with a stereo microscope (Leica MZ16F Binocular UV microscope).

2.5.2 Vacuolar staining

To visualize vacuoles, 5-7-days old seedlings were stained with flouresceine diacetate (FDA), 2',7'-Bis-(2-Carboxyethyl)-5-(and-6)-Carboxyfluorescein, Acetoxymethyl Ester (BCECF-AM) and *N*-(3-Triethylammoniumpropyl)-4-(6-(4-(Diethylamino) Phenyl) Hexatrienyl) Pyridinium Dibromide (FM4-64).

FDA solution was prepared as a 5mg/ml stock in acetone and kept in 4°C until used. FDA stock solution was diluted in 1:1000 in half-strength MS medium and incubated with seedlings for 30 minutes. Before visualization, seedlings were washed three times to remove excess dye with half-strength MS medium. Samples were excited with 494nm laser line, and emission collection was set at 505-525nm.

BCECF-AM was prepared as a 10mM stock solution and diluted in 1:1000 in half-strength MS medium for staining. Seedlings were incubated with staining solution for 20 minutes. Seedlings were washed twice with half-strength MS medium. Samples were excited with 488nm laser line and detection length was 520-550nm.

FM4-64 was prepared as a 0.5%(w/v) stock solution in DMSO and diluted

2. MATERIALS AND METHODS

in 1:1000 in half-strength MS medium for staining. Seedlings were incubated with ice-cold staining solution for 5 minutes and at room temperature for 20-30 minutes. Seedlings were washed twice with half-strength MS medium. Samples were excited with 488nm laser line, and signal was detected at 625-665nm.

2.5.3 Pavement cell complexity measurement

Pavement cell complexity measurements were performed by preparing epidermal agarose imprints as described in Mathur and Koncz (1997). Cotyledons were placed on setting 3%(w/v) low-melting agarose (Biozym Scientific) in water and refrigerated until completely set. The imprints were visualized and imaged using differential interference contrast microscopy (DIC) (Leica DM5000B). Measurements were taken from four cells each from five plants using circularity function built in ImageJ (Schneider et al., 2012).

2.5.4 GUS-staining

Transgenic *pCFS1::GUS* plants were plated on half strength MS medium for several time points to examine β -glucuronidase (GUS) expression driven by *CFS1* promoter. Plant materials were incubated in GUS staining solution (50mM sodium phosphate buffer (pH = 7.2), 2mM potassium ferrocyanide, 2mM potassium ferricyanide, 2mM X-Gluc, 0.2% Triton X-100) and gently vacuum infiltrated for 15 minutes. Samples were incubated in staining solution at 37°C for 6-24 hours.

To observation the staining pattern with stereo microscope, chlorophyll of stained samples were cleared by rinsing with water and incubate in increasing concentration of ethanol (20%(v/v), 35%(v/v), 50%(v/v), 70%(v/v)) each for 2 hours at room temperature.

2.5.5 *elch*-trichome analysis

The number of wild-type and *elch* trichome were observed with stereo microscope and counted manually. The difference in the ratio of *elch*-trichomes to

all trichomes between genotypes was tested using Fisher's exact test and Pearson's χ^2 test of independence.

2.5.6 Fluorescence microscopy

Fluorescent signal from transiently expressed plants and stable transgenic lines were screened with a stereo microscope (Leica MZ16F) and a fluorescent microscope (Leica DMRA2).

2.5.7 Confocal laser scanning microscopy

All observations made with confocal laser scanning microscopy (CLSM) were done using either Leica TSC SPE or Leica TSC SP8. Subsequent image analysis was performed with ImageJ2/Fiji software (Schindelin et al., 2012, 2015).

2.5.8 Transmission electron microscopy

For transmission electron microscopy (TEM), leaf 1 and 2 from Col-0 and *cfs1* from 25-30 day-old plants were collected, immediately fixed in fixation solution (2.5%(v/v) glutaraldehyde, 2%(v/v) paraformaldehyde, 80mM HEPES buffer pH =7.0) and washed three times in the HEPES buffer.

Britta Müller performed all the processes after fixation. Postfixation was conducted in 1% OsO_4 in 80mM HEPES buffer (pH =7) for 2 hours at room temperature followed by washing 3 times in the HEPES buffer and treated with 1% (w/v) uranylacetate in HEPES buffer overnight in the dark at 4°C. Dehydration was achieved by washing in increasing acetone concentration (10%(v/v), 20%(v/v), 30%(v/v), 50%(v/v), 70%(v/v), 90%(v/v), 95%(v/v), 100% (v/v) acetone) on ice. SPURR resin (SPURR:acetone in 1:3, 1:1, 3:1, 1:0) were infiltrated to samples for 2h for each combination and for 1:0 SPURR:acetone, dehydrated samples were polymerized overnight at 70°C (Spurr, 1969). Semi-thin sections (1 μ M) and 60-80 nm ultra-thin sections were prepared with a Leica EM UC7 microtome equipped with a DiATOME diamond knife at 45° angle. Semi-thin sections were stained with a 1%(v/v) toluidine blue in 1% Borax: 1% Pyronin G solution (5 : 1). Ultrathin sections were mounted on pioloform cov-

2. MATERIALS AND METHODS

ered with 1mm copper grids, contrasted with Reynolds lead citrate (Reynolds, 1963) for one minute and observed with a Philips CM10 TEM. Micrographs were taken with an Orius SC200W CCD camera equipped with the DigitalMicrograph software (Gatan Inc.).

2.6 Biochemical methods

2.6.1 Sample preparation

Samples for western blot were prepared according to Zhou et al. (2013) with some modifications. Plant materials from various stages were collected and ground in liquid nitrogen using a mortar. Detergent protein extraction buffer (100mM Tris/HCl (pH = 8.0), 10mM NaCl, 1mM EDTA (pH = 8.0), 1%(v/v) Triton X-100, 0.2% β -mercaptoethanol, 25mM *N*-Ethylmaleimide) was immediately added to the sample, and the lysate was filtered through 210 μ m and 70 μ m nylon mesh to obtain crude extract.

To ensure equal amount of total protein for subsequent experiments, crude extract was mixed with Laemmli buffer (50mM Tris/HCl (pH=6.8), 2%(w/v) SDS, 10%(v/v) glycerol, 0.01%(w/v) bromophenol blue, 100mM DTT), heated for 5 minutes at 95°C and separated by SDS-Polyacrylamide gel electrophoresis (PAGE) at constant 25mA per gel. Polyacrylamide gels were rinsed several time with distilled water and stained with colloidal Coomassie blue solution (10%(w/v) ammonium sulfate, 0.1% Coomassie Brilliant Blue G-250, 3%(v/v) *ortho*-phosphoric acid, 20%(v/v) ethanol) for 4-16 hours. The gels were destained several times in water. Total protein amount was quantified and adjusted with Laemmli buffer according to an area size of an approximately 55kDa RIBULOSE-1,5-BISPHOSPHATE CARBOXYLASE/OXYGENASE (RuBisCO) band. Calculation was performed using Gel analysis function in ImageJ2/Fiji software (Schindelin et al., 2012, 2015).

2.6.2 Western blot

Separated proteins on polyacrylamide gels were transferred to PVDF membrane in semi-dry condition. The transfer was performed at constant 2.5 mA per transfer hour at 4°C. The presence of PageRuler™ prestained protein ladder (Thermo Scientific) on membrane was used to determine successful and complete transfer of proteins onto membranes.

Table 2.9: List of antibodies used in this study

Antibody	Clonality	Predicted size (kDa)	Host	Dilution	Lot number
Primary antibody					
anti-ATG8a (abcam; ab77003)	Polyclonal	14	rabbit	1:500	GR193264-1
anti-cFBPase (Agrisera; AS04 043)	Polyclonal	45/37	rabbit	1:5000	1104
anti-NBR1 (Agrisera; AS14 2805)	Polyclonal	100/75	rabbit	1:2000	1410
anti-Ub(P4D1) (Santa Cruz; sc-8017)	Monoclonal		mouse	1:500	G0913
Secondary antibody					
anti-mouse (JacksonImmuno; 115-035-003)	Polyclonal		goat	1:5000	107936
anti-rabbit (Sigma-Aldrich; A6154)	Polyclonal		goat	1:5000	SLBK2462V

For detection with anti-Ub(P4D1), proteins blotted onto membrane were denatured by incubating in denaturing buffer (6M Guanidine hydrochloride, 20mM Tris, 5mM β -mercaptoethanol and 1mM phenylmethylsulfonyl fluoride) for 30 minutes at 4°C under agitation. The membrane was washed in phosphate buffered saline Tween-20 (PBST) solution (137mM NaCl, 12mM Phosphate, 2.7mM KCl, 1%(v/v) Tween-20, pH = 7.4) for 15 minutes three times at room temperature. Blocking was done with 3%(w/v) bovine serum albumin (BSA) in PBST for one hour at room temperature under agitation.

For anti-cytosolic FRUCTOSE-1,6-BISPHOSPHATASE (cFBPase) and anti-NBR1 detection, membranes were blocked with 3%(w/v) skimmed milk powder in PBST for one hour at room temperature under agitation. Anti-ATG8a

2. MATERIALS AND METHODS

detection were blocked in 5%BSA(w/v) in PBST for two hours at room temperature under agitation. Primary antibody was diluted in PBST (see Table 2.9) and incubated with membranes for one hour at room temperature under agitation. The membranes were washed in PBST three times, each for 15 minutes under agitation. Anti-mouse and anti-rabbit conjugated with horse radish peroxidase (HRP) were diluted in PBST (see Table 2.9) and incubated with the membranes for one hour at room temperature under agitation. The membranes were washed in PBST for 15 minutes three times before adding chemiluminescent substrate from SuperSignal[®] West Femto Maximum Sensitivity Substrate kit (Thermo Scientific). HRP signal was exposed and recorded every 10 seconds in increment by a light-sensitive CCD camera (Fujifilm LAS-4000mini).

2.7 Statistical analysis and graphical representation

All descriptive statistics and statistical tests were performed using R statistical programming language 3.2.1 "World-Famous Astronaut" (R Core Team, 2014) in RStudio environment (RStudio Team, 2015). The following additional R-programming packages were used: *plyr* package (Wickham, 2011) for summary of descriptive statistics; *reshape2* package for data organization (Wickham, 2007); *multcomp* package and its dependencies (Hothorn et al., 2008) for Tukey's honest significance difference test after ANOVA analysis. All graphical representation was generated using *ggplot2* package (Wickham, 2009). The package *scales* was used for y-axis-transformation (Wickham, 2015). Figures are compiled using the Inkscape 0.91.

3. Results

CFS1 emerged along with *CFS2* from a previous bioinformatic screen as a potential plant ESCRT-0 component that could recognize ubiquitinated proteins and recruit ELCH, the core ESCRT-I component, to late endosomes (Shahriari, 2008). *CFS1* interacts with ELCH (Herberth, 2012) but has no influences on ELCH localization on endosomes (Sutipatanasomboon, 2012). Its SYLF domain binds to PI3P and actin instead of ubiquitin, negating the ESCRT-0 equivalence hypothesis (Herberth, 2012). As several dysfunctional ESCRT-component mutants in yeast and mammalian system show an autonomous cell death phenotype (Wegner et al., 2011), the cell death phenotype in *cfs1* mutants offered an alternative explanation for its ESCRT-related function.

3.1 *pCFS1-gCFS1* can complement *cfs1* phenotype

In my MSc thesis, I could show that the lesion mimic phenotype could be rescued by expressing *CFS1* under the control of 35s promoter in both null (*cfs1-1* and *cfs1-2*) and non-null (*cfs1-3*) mutants (Sutipatanasomboon, 2012). To ascertain that the endogenous level of *CFS1* expression is sufficient to complement the cell death phenotype in *cfs1*, the genomic region including the upstream promoter region (Figure 2.1) was introduced to *cfs1-2* mutants (*pCFS1-gCFS1* in *cfs1-2*).

In *cfs1-2* background, 12 T1 plants were isolated by glufosinate resistance, and four lines were analyzed in the T2 generation. In all lines studied, the majority were wild-type like, while the minority still showed lesions (Figure 3.1 and Table 3.1). This minor fraction were all susceptible to glufosinate, and the number of individuals in each line did not deviated from 25% (p-value = 0.6703, 0.1693, 0.8163 and 0.93 for each line respectively. Statistical test is shown in Appendix A). This demonstrate that the lesion mimic phenotype in *cfs1* is recessive and was caused by the lack of functional *CFS1*.

3. RESULTS

Figure 3.1: *pCFS1-gCFS1* complements the *cfs1-2* mutant phenotype - Representative of 30-day old Col-0, *cfs1-2* and *cfs1-2* mutant complemented with *pCFS1-gCFS1*. Boxed regions are digitally magnified in the figures below. Scale bars: 1cm.

Table 3.1: Number of T2 *cfs1-2* plants complemented by *pCFS1-gCFS1*

Line	N_{WT}	N_{lesion}	N_{all}
1	45	9	54
2	46	3	49
3	24	6	30
4	40	12	52

N_{WT} : Number of plants wild-type like plants
 N_{lesion} : Number of plants showing lesions
 N_{all} : Total number of plants analyzed

3.2 Cell death in *cfs1* mutants

The cell phenotype was characterized in details to discern which type of cell death occurred in *cfs1* mutant, which could reveal the possible pathway *CFS1* is involved in. The development of *cfs1* leaves was phenotypically analyzed to rule out a possible defect in leaf development. Seeds of Col-0, *cfs1-1*, *cfs1-2*, *cfs1-3* and *cfs1* non-null homologue, *cfs2* were randomly grown in the same tray. Total leaf numbers and that of leaf showing lesions were recorded every two days until flower bud started to form.

At all observation points, total leaf number of plants were comparable in every genotype (Figure 3.2b). Nevertheless, after *cfs1* mutants started to produce leaf 5 or 6, lesions surrounding the leaf veins became visible in leaf 1 and in some cases, leaf 2; while the first and second leaf of Col-0 and *cfs2* appeared healthy (Figure 3.2). Over time, lesion formation progressed to leaves 3 and 4 until flower buds started to be appear. By the time all plants have flowered (33 days after sowing), lesions did not progress beyond the last observation point and were visible in 100% of *cfs1-1* (n=15), 92.31% of *cfs1-2* (n=13) and

Figure 3.2: All *cfs1* mutants form lesions before flowering -

a) Representatives of 23-days old Col-0, *cfs1-1*, *cfs1-2*, *cfs1-3* and *cfs2* plants. Boxed regions are digitally magnified in the figures below. Scale bars: 1 cm. Photos were taken by Siegfried Werth.

b) Graphical representation of Col-0, *cfs1-1*, *cfs1-2*, *cfs1-3* and *cfs2* leaf development. The genotypes are represented by colors, total leaf numbers by circle and the number of leaves showing lesions by square. The arrow indicates the day flower bud formation was visible. The complete data set and its summary are shown in Appendix B.

3. RESULTS

100% of *cfs1-3* (n=15) plants. (See Table B.2 for a summary of each observation point). Altogether, this establishes that, apart from lesion formation in the eldest leaves, *cfs1* mutants do not develop differently than Col-0 under the condition studied.

3.2.1 Cell death in *cfs1* only occurs in palisade cells

To illustrate where cell death in *cfs1* mutants occurs and in which cell type, *cfs1* leaves showing lesions were stained with trypan blue (Figure 3.3a) and toluidine blue for sectioning (Figure 3.3b). Trypan blue staining showed that cell death in *cfs1* mutants occurred in the non-epidermal layer (Figure 3.3a). Semi-thin sections stained with toluidine blue revealed that cell death was restricted to the mesophyll layer and occurred only in palisade cells (Figure 3.3b), which corroborated the observation seen by trypan blue staining.

Figure 3.3: Cell death in *cfs1* mutants occurs in palisade cells -

a) Trypan blue staining of leaf 1 or 2 of Col-0, *cfs1-1*, *cfs1-2* and *cfs1-3*. Scale bar: 1mm.

b) Toluidine blue staining of leaf 1 or 2 of Col-0, *cfs1-1*, *cfs1-2* and *cfs1-3* semi-thin sections. Arrowheads indicate stained dead cells. Sectioning and imaging were performed by Britta Müller.

3.2.2 *CFS1* promoter activity changes in an age-dependent manner

The specificity of cell death in *cfs1* mutants poses the question whether *CFS1* activity is restricted to the palisade cells. To address this, a GUS reporter gene driven by *pCFS1* was introduced to Col-0 plants. The promoter activity was observed 25 days after sowing (DAS), the time point that lesions were visible in all leaf 1 and 2 of *cfs1* mutants (Table B.2). Staining pattern showed that in leaves 1 and 2, the promoter activity was restricted to the leaf veins (Figure 3.4, leaf 2 in line 1 and leaf 1 in line 2). Whereas in younger and emerging true leaves, the activity was observed in all layers and cell types (Figure 3.4, leaf 8 in line 1 and leaf 5 in line 2).

Figure 3.4: GUS activity of *pCFS1* - GUS staining of *pCFS1*-GUS in Col-0 at 25, 14 and 5 DAS. Boxed leaves are magnified and shown next to the figure with the number indicating the leaf number. Cotyledons are indicated as c. Scale bar: 1mm.

At a younger age (14 DAS), the promoter activity in leaves 1 and 2 was similar to leaves 3 and 4 of an older stage; while promoter activity was indistinguishable between leaves 3 and 4 to those of the emerging leaves of an older stage (Figure 3.4, 14 DAS). In seedling stage, the GUS expression in cotyledon was ubiquitous, in contrast to those in the older stage (Figure 3.4, 5 DAS). Taken all stages together, the pattern of GUS activity driven by *pCFS1* shows that *CFS1* expression is not restricted to palisade cells and differs in an age-dependent manner.

3. RESULTS

3.2.3 Cell death in *cfs1* show HR-cell death characteristics

To distinguish whether cell death observed in *cfs1* mutants is associated with developmental or stress-response processes, dead *cfs1-2* cells were visualized in a higher magnification using transmission electron microscopy (TEM). In all *cfs1-2* dead cells, cell remnant was present (Figure 3.5a), opposite to an 'empty-walled cell corpse' that is typical of a developmental-related cell death (van Doorn et al., 2011; van Doorn, 2011). Furthermore, the cell wall between lived and dead *cfs1-2* cells has thickened (Figure 3.5b), which is a characteristic of hypersensitive response (HR)-cell death (Dickman and de Figueiredo, 2011).

Figure 3.5: *cfs1* mutants show HR-cell death characteristics -

a) TEM image of dead *cfs1-2* palisade cells. Scale bar is 2 μ m.

b) TEM image of the cell wall between lived (left) and dead (right) *cfs1-2* palisade cells. Scale bar is 1 μ m. cw: cell wall; th: cell wall thickening.

Britta Müller performed postfixation, sectioning and imaging of Figure 3.5a, b.

c) Comparative transcript levels of *PR1*, *PR2*, *PR5*, *SAG13* and *WRKY53* in leaves 1 and 2 of *cfs1-2* and *cfs1-3* showing lesions. The expression was normalized with *EF1α* and calibrated to Col-0 of the same age. Y-axis is plotted in log₁₀ scale. Error bars represent standard error. Asterisks indicate a significant difference at $p \leq 0.05$ level and squares at $p \leq 0.1$ level. Statistical tests are shown in Appendix C.

To further test if cell death in *cfs1* mutants is related to HR, the expression of HR-related genes, *PATHOGENESIS-RELATED GENE 1,2,5* (*PR1*, *PR2* and *PR5*, respectively) and *SENESCENCE-ASSOCIATED-GENE 13* (*SAG13*) (Brodersen et al., 2002) were examined by Real-time quantitative reverse transcription PCR (RT-qPCR). In *cfs1-2* and *cfs1-3* leaves 1 and 2 showing lesions, transcript levels of *PR1*, *PR2*, *PR5* and *SAG13* were slightly up-regulated, ranging from 10-35, 5-15, 3-15 and 2-5 fold, respectively (Figure 3.5c; fold change for each allele is shown in Table C.2). For *cfs1-3*, the expression of *PR1*, *PR2* and *PR5* were significantly different from Col-0 ($p = 0.0145$, $p = 0.0177$, $p = 0.0353$, respectively.) In case of *SAG13*, the expression in *cfs1-2* is significantly different from Col-0 ($p = 0.0446$). Conversely, the transcript levels of an age-dependent senescence gene, *WRKY53* (Hinderhofer and Zentgraf, 2001) were not differentially expressed in *cfs1-2* or *cfs1-3* when compared to Col-0 (Figure 3.5c; fold change is shown in Table C.2 and statistical analysis in Appendix C). The HR-cell death and the constitutive expression of *PR1*, *PR2* and *PR5* establish that *cfs1* is a lesion-mimic mutant (LMM) that displays an autoimmune phenotype (Lorrain et al., 2003; Palma et al., 2010).

3.2.4 The involvement of *CFS1* in HR-cell death

The microscopic morphology of dead *cfs1* cells (Figure 3.5a, b), and the slight up-regulation of HR-related marker genes (Figure 3.5c) suggest an involvement of *CFS1* in cell death following HR. An additional connection to HR-cell death comes from *CFS1* interactions with PRENYLATED RAB ACCEPTOR 1.F3 (*PRA1.F3*) and with BINDING PARTNER OF ACD11-1 (*BPA1*) (Herberth, 2012), both known as interactors of another LLM protein, ACCELERATED CELL DEATH 11 (*ACD11*) (Petersen et al., 2009).

Mutant *acd11* also exhibits autoimmune phenotype (Palma et al., 2010). It displays a ‘runaway cell death’, in which death propagates to the neighboring healthy cells and engulfs the entire leaf before the plant can flower (Brodersen et al., 2002). The phenotype is identical to plants over-expressing *APOPTOSIS-LINKED GENE 2-INTERACTING PROTEIN X* (*ALIX*) (Personal communication S Schellmann), an accessory ESCRT-III subunit that interacts with mam-

3. RESULTS

malian ELCH counterpart, TUMOUR SUSCEPTIBILITY GENE 101 (TSG101) (Mahul-Mellier et al., 2006). Similar to *cfs1*, the transcript levels of *PR1*, *PR2*, *PR5* and *SAG13* are also up-regulated in *acd11* (Brodersen et al., 2002). Taken the phenotypic similarities of ALIX over-expression and *cfs1* plants to *acd11* into account and ALIX interaction with mammalian ELCH homologue, I hypothesized that the involvement of the ESCRT-complex in plant cell death is through the ACD11-related cell death pathway. Hence, cell death seen in *cfs1* mutants could be a reflection of a less severe *acd11* runaway cell death.

3.2.4.1 Cell death in *cfs1* is dependent on EDS1-activated effector-triggered immunity

If cell death in *cfs1* was a milder form of *acd11* cell death, the *cfs1* phenotype would then be dependent on functional *acd11* suppressors. To test this hypothesis, *cfs1-2* was crossed to two of the *acd11* cell death suppressors *lazarus1* (*laz1*) and *enhanced disease susceptibility 1* (*eds1*) (Malinovsky et al., 2010; Brodersen et al., 2002). Under a normal greenhouse condition, neither *cfs1-2 laz1-5* nor *cfs1-2 eds1-2* developed visible lesions when *cfs1* did (Figure 3.6a).

EDS1 is a lipase-like protein that activates effector-triggered immunity (ETI) (Aarts et al., 1998; Wiermer et al., 2005). When ETI is activated, it results in HR and other overlapping cellular responses (Wiermer et al., 2005; Coll et al., 2011). ETI responses are inhibited at ambient elevated temperatures (28-32°C) that in turn significantly reduce HR-cell death (Cheng et al., 2013; Wang et al., 2009). To further establish whether HR-cell death in *cfs1* is attested to ETI, *cfs1* mutants were shifted to 28°C after germination. As a result, at 30 DAS, 100% in *cfs1-1* (n = 19), 95% in *cfs1-2* (n = 20) and 100% in *cfs1-3* (n = 19) still had not developed lesions (Figure 3.6b), demonstrating that HR-cell death in *cfs1* mutants results from the activation of ETI.

3.2.4.2 Cell death in *cfs1* does not require SA signaling

HR occurs in concert with several signaling cascades and molecular events. Together, they kill uninjured cells surrounding the compromised cells and prime the plants to cope with and fight against pathogen attack (Wiermer

Figure 3.6: Cell death in *cfs1-2* mutants requires a functional EDS1 signaling pathway -

a) Representatives of 27-days old Col-0, *cfs1-2*, *laz1-5*, *cfs1-2 laz1-5*, *eds1* and *cfs1-2 eds1-2* grown in greenhouse condition.

b) Representatives of 27-days old *cfs1-1*, *cfs1-2* and *cfs1-3* grown at 28°C.

Scale bar: 1cm. All images were taken by Siegfried Werth.

et al., 2005; Coll et al., 2011). In *acd11*-related cell death, this murderous command relies, in most part, on a SA-signaling cascade (Brodersen et al., 2002, 2005). The expression of the bacterial enzyme naphthalene hydroxylase G (*nahG*) that degrades SA and other isochorismate-derived compounds (Serrano et al., 2013) completely restores *acd11* to wild-type phenotype (Brodersen et al., 2002). It was also demonstrated that the *acd11* runaway cell death phenotype is depended on a functional SA biosynthesis enzyme, *ISOCHORISMATE SYNTHASE 1 (ICS1)* encoded by *SALICYLIC ACID INDUCTION DEFICIENT 2 (SID2)* but not *ENHANCED DISEASE SUSCEPTIBILITY 5 (EDS5)*-dependent SA export to cytoplasm (Brodersen et al., 2005).

To investigate if functional SA signaling is necessary for the execution of cell death in *cfs1* mutant, *nahG* was introduced to *cfs1-2*, and double mutant *cfs1-2 sid2-1* and *cfs1-2 eds5-1* were generated. As a result, none of the SA-deficient *cfs1-2* plants showed phenotype suppression (Figure 3.7), demonstrating that the execution of cell death in the *cfs1* mutant does not require functional SA signaling as in *acd11*.

3. RESULTS

Figure 3.7: **Cell death in *cfs1-2* mutants is independent of SA-signalling** - Representatives of 25 DAS Col-0, *cfs1-2*, *nahG* in Col-0 (*nahG/Col-0*), *nahG* in *cfs1-2* (*nahG/cfs1-2*), *sid2-1*, *cfs1-2 sid2-1*, *eds5-1* and *cfs1-2 eds5-1* grown in the greenhouse condition. Scale bar: 1 mm. Images were taken by Siegfried Werth.

The independence of *cfs1* cell death on the SA-signaling pathway contradicts the hypothesis that *cfs1* cell death is a milder manifestation of *acd11* cell death and poses the question which signaling pathway brings about *cfs1* cell death. Because EDS1 also assists in a crosstalk between SA to ethylene and jasmonic acid (JA)-signaling pathways (Wiermer et al., 2005), I checked for possible deregulation of both pathways in *cfs1* mutant using *ETHYLENE RESPONSIVE FACTOR 1* (*ERF1*) (Tintor et al., 2013) and *PATHOGENESIS-RELATED GENE 3* (*PR3*) (Abe et al., 2013) as ethylene-responsive marker genes. *VEGETATIVE STORAGE PROTEIN2* (*VSP2*) and *PLANT DEFENSIN 1.2* (*PDF1.2*) served as JA and ethylene-responsive marker genes (Lorrain et al., 2003), while *LIPOXYGENASE 2* (*LOX2*) responds only to JA (Danisman et al., 2012).

In *cfs1-2* and *cfs1-3* leaves 1 and 2 showing lesions, the transcript levels of *ERF1*, *LOX2*, and *VSP2* were comparable to Col-0 leaves 1 and 2 of the same age (Figure 3.8a; fold change in each allele are shown in Table D.2). For *PR3* and *PDF1.2*, the expression in *cfs1-2* were slightly up-regulated, but only *PR3* was significantly different from Col-0 ($p = 0.00674$); however, this is likely a side-effect of SA-accumulation as both markers have been reported to also respond to SA-accumulation (Yoshimoto et al., 2009).

In addition to JA and ethylene crosstalk signaling, it is also possible that

3.2 Cell death in *cfs1* mutants

Figure 3.8: JA, ethylene, ROS and cell death executor transcript levels in *cfs1* - Fold change expression of leaves 1 and 2 of *cfs1-2* and *cfs1-3* compared to that of Col-0 using **a)** *ERF1*, *LOX2*, *PDF1.2*, *PR3* and *VSP2* as JA and ethylene-responsive marker genes. **b)** *GLY3*, *RD21*, *FES1A* and *UGT87E2* as oxidative stress genes. **c)** *MC1*, *MC9*, *RNS3*, *BFN1* and *CAN1* as cell death execution genes.

The expression levels were normalized to *EF1α*. Y-axis is plotted in log₁₀ scale; error bars represent standard error. Two asterisks indicate a significant difference at $p \leq 0.01$ level. Statistical tests for Figure 3.8a are shown in Appendix D and Figure 3.8b,c in Appendix E.

cfs1 cell death relies on other signaling branches that are concurrent to HR-cell death, for example, the generation of reactive oxygen species (ROS) and the initiation of caspase-like protease activity that execute cell death (Coll et al., 2011). To check for any indication of *cfs1* cell death involvement to these signaling branches, the expression of oxidative stress response marker genes, *GLY-*

3. RESULTS

OXALASE 3 (GLY3), *RESPONSIVE TO DEHYDRATION 21 (RD21)* (Martínez-Fábregas et al., 2014), *FACTOR EXCHANGE FOR SSA1 PROTEIN1A (FES1A)* and *URIDINE DIPHOSPHATE GLYCOSYLTRANSFERASE 74E2 (UGT74E2)* (Hackenberg et al., 2013) were examined to check for an increase in ROS production. *METACASPASE 1* and *9 (MC1, MC9, respectively)* (Coll et al., 2011), *RIBONUCLEASE 3 (RNS3)*, *BIFUNCTIONAL NUCLEASE 1 (BFN1)* and *CALCIUM DEPENDENT NUCLEASE 1 (CAN1)* are cell death executor genes that served as marker genes for the initiation of caspase-like protease activity (Van Hautegeem et al. 2015; Personal communication M Nowack). None of the marker genes investigated showed a differential expression when compared to Col-0 (Figure 3.8b, c; see Appendix E for fold change of each marker gene and statistical tests)

To sum up, the examination of JA, ethylene, oxidative stress and caspase-like proteases marker genes showed no indication that *cfs1* cell death command came from or was executed by any of these signaling branches.

3.3 *CFS1* function in ESCRT-related trafficking

Due to the lack of any indication which signaling pathway is involved in *cfs1*, I turn to consider it from the ESCRT-related trafficking perspective. To undertake this, two main questions were put forward. First, if the lack of functional *cfs1* has an impact on ESCRT-related trafficking; and second, how and if cell death in *cfs1* mutant is influenced by the function of the ESCRT-I complex.

3.3.1 *cfs1* mutants show normal endomembrane architecture

Because *CFS1* has been shown to bind specifically to PI3P, which is associated with endosomes (Herberth, 2012), the endomembrane architecture was examined for aberrant endosomes similar to *class E* compartment (Raymond et al., 1992) to address the first question. Non-colocalizing endosomal markers, mCherry-VTI12 and mCherry-SYP61 and co-localizing markers, mCherry-ARA7 were stably expressed and YFP-ELCH (Herberth, 2012) were transiently expressed and imaged in *cfs1-2* and Col-0. In none of endosomal markers ex-

3.3 *CFS1* function in ESCRT-related trafficking

amined was there any obvious aberrant endosomes similar to *class E* compartment observed in *cfs1-2* (Figure 3.9).

Figure 3.9: Lack of functional *CFS1* does not affect endomembrane architecture - CLSM images of endosomal markers VTI12, SYP61 and ARA7 were stably expressed, and fluorescent ESCRT-I component ELCH was transiently expressed in Col-0 and *cfs1-2*. Scale bar: 25 μ m.

In addition to the connection to endosomes, the ESCRT-complex is also linked to vacuole maintenance (Shahriari et al., 2010b; Michailat and Mayer, 2013; Cai et al., 2014; Kalinowska et al., 2015). One striking example is SUPPRESSOR OF K⁽⁺⁾ TRANSPORT GROWTH DEFECT1 (SKD1) that disassembles the ESCRT-complex from the endosomal membrane (Haas et al., 2007). Lack of a functional SKD1 (Cai et al., 2014) and the overexpression of its dominant-negative form in tobacco cells, *Arabidopsis* cell culture (Haas et al., 2007) and trichome cell (Shahriari, 2008; Shahriari et al., 2010b) result in cell death following vacuole loss or fragmentation. To check if this is also the case in *cfs1-2* cell death, vacuoles were stained using BCECF-AM (direct staining), FDA and FM4-64 (indirect stainings). None of these vacuolar staining methods reveal an abnormal vacuole morphology in *cfs1-2* mutants (Figure 3.10).

3.3.2 No alteration in actin cytoskeleton in *cfs1* mutants

Another biochemical property of CFS1 is the actin binding its SYLF domain (Herberth, 2012). As actin dynamics have been proposed to play an active role

3. RESULTS

Figure 3.10: **Lack of functional *CFS1* does not affect vacuole maintenance** - CLSM images of Col-0 and *cfs1-2* seedlings stained with BCECF-AM, FDA and FM4-64 show intact vacuole. Scale bar: 50 μ m.

in cell-death signaling (Smertenko and Franklin-Tong, 2011), possible changes in actin cytoskeleton morphology were screened by analyzing the localization of Lifeact-eGFP and by pavement cell complexity in *cfs1-2* and *cfs1-3*. Neither methods showed any obvious alteration of the actin cytoskeleton when *CFS1* function was removed (Figure 3.11).

Figure 3.11: **Lack of functional *CFS1* does not affect actin cytoskeleton** - No abnormality in actin cytoskeleton in compared to Col-0 as shown in a) stable expression of Lifeact-eGFP in Col-0, *cfs1-2* and *cfs1-3*. Scale bar: 25 μ m. b) the pavement cell complexity of Col-0, *cfs1-2* and *cfs1-3*. The box plot summarizes the circularity of 20 cells from each genotype. Dots indicate outliers and crosses the mean of circularity. Circularity values and descriptive statistics are shown in Appendix F.

3.3.3 Cytokinesis defects are alleviated in *cfs1-2 elch*

One of the *Arabidopsis* ESCRT-I core components, *elch* shows a defect in cytokinesis that is translated into the formation of the *elch*-trichome (Spitzer et al.,

3.3 CFS1 function in ESCRT-related trafficking

2006). The *elch*-trichome is an appearance of two trichomes stemming from a single pavement cell (Figure 1.5 and Spitzer et al. 2006). The phenotype is only present in about 2% of all trichomes in *elch* and is enhanced when additional ESCRT-I components are mutated (Spitzer et al., 2006; Keshavaiah, 2008). To further address if lack of functional CFS1 plays a role in the ESCRT-I function, the level of deficiency in cytokinesis in *cfs1-2 elch* mutant was inspected.

Table 3.2: Wild-type and *elch* trichome number in Col-0, *cfs1-2*, *cfs1-2 elch*, *elch* and Ws-2

Genotype	Trichome _{Wild-type}	Trichome _{elch}	All trichomes	% <i>elch</i>	N _{WT}	N _{elch}	N _{all}
Col-0	2353	0	2353	0.000	22	0	22
<i>cfs1-2</i>	2633	0	2633	0.000	24	0	24
<i>cfs1-2 elch</i>	3819	16	3835	0.417	36	12	36
<i>elch</i>	4014	47	4061	1.157	30	21	30
Ws-2	1733	0	1733	0.000	14	0	14

%*elch*: Percentage of the number of *elch* trichomes to the number of all trichomes

N_{WT}: Number of leaves showing wild-type trichomes

N_{elch}: Number of leaves showing *elch* trichomes

N_{all}: Number of all leaves counted

Data in the table are a summary of Table H.1. Summary by leaf number is displayed in Table H.2. All statistical tests are shown in Appendix H.

In *cfs1-2 elch* mutant, only 0.42% of *elch*-trichome were present in contrast to 1.16% in *elch*. Two statistical analyses (Fisher's exact test and Pearson's χ^2 test of independence) showed that 0.42% and 1.16% are not equal ($p=3.666e^{-05}$ and $p=0.0002228$, respectively) but 0.42% is less ($p = 2.428e^{-05}$ and $p = 0.0002228$, respectively) than 1.16% (Table 3.2). This shows that the lack of *cfs1* function alleviates cytokinesis effect in *elch* and suggests an influence of *CFS1* on *ELCH* function.

3.3.4 Cell death in *cfs1* is not dependent on ESCRT-I function

To address whether the ESCRT-I complex function influences cell death in *cfs1*, *cfs1-2* mutant was crossed to its ESCRT-I interactor *elch*, and other non-interacting ESCRT-I components, *vps28.2* and *vps31.7*. At 20 DAS, 63.6% of *cfs1-2* (n = 33) , 64.5% of double mutant *cfs1-2 vps28.2* (n=35) and 52.5% of *cfs1-*

3. RESULTS

2 vps37.1 (n=34) developed lesions in leaves 1 and 2 (Figure 3.12). In *cfs1-2 elch* at 20DAS, however, no visible lesions were observed (n=35; Figure 3.12 and Table G.2). At 25 DAS, 90.9% of *cfs1-2*, 82.5% of *cfs1-2 vps28.2* and 100% of *cfs1-2 vps37.1* have formed lesion, but only 42.9% of *cfs1-2 elch* showed the cell death phenotype (Figure 3.12 and Table G.2). According to Pearson's χ^2 test of independence, the fraction of *cfs1-2 elch* plants showing lesions at 25 DAS is significantly different from the fraction of *cfs1-2* plants (90.2%) showing lesions at the same stage ($p = 2.841e^{-05}$). By 30 DAS, however, 82.86% of *cfs1-2 elch* showed the cell death phenotype, which is comparable to the percentage of *cfs1-2* plants showing cell death phenotype at the same stage ($p = 0.1563$; Table G.2). This illustrates that cell-death in *cfs1* mutant does not require a fully functional ESCRT-I complex. Nevertheless, the lack of a functional *ELCH* may impact how *cfs1-2* cell death progresses.

3.3 *CFS1* function in ESCRT-related trafficking

Figure 3.12: Cell death in *cfs1* mutants is independent of a functional ESCRT-I component -

a) Representatives of 25-days old *Ws-2*, *elch*, *cfs1-2 elch*, *Col-0*, *vps28.2*, *cfs1-2 vps28.2*, *vps37.1* and *cfs1-2 vps37.1* plants. Boxed regions are magnified in the figures below. Scale bar: 1cm. All photos were taken by Siegfried Werth.

b) Graphical representation of the total number of *Ws-2*, *elch*, *cfs1-2 elch*, *Col-0*, *vps28.2*, *cfs1-2 vps28.2*, *vps37.1* and *cfs1-2 vps37.1* leaves and those of leaves showing lesions. Circle represents total leaf number and square the number of leaves showing lesions. Each genotype is represented by color. The complete data set and its summary are shown in Appendix G.

3. RESULTS

3.3.5 Mature *cfs1* mutants accumulate ubiquitinated proteins

The principle function of the ESCRT-complex is to target ubiquitinated proteins and sort them into late endosomes, forming multivesicular bodies (MVBs) that are subsequently delivered to vacuole for degradation (Katzmann et al., 2001). It has been demonstrated in *elch* and *elch vps28.2 vps37.1* (i^3) mutants that the deficiency of the ESCRT-I complex resulted in an accumulation of ubiquitinated proteins (Personal communication S Schellmann). To answer if *CFS1* influences the role of ELCH in this aspect, *cfs1* and *cfs1-2 elch* were probed with ubiquitin antibody (anti-Ub(P4D1)) for ubiquitinated proteins accumulation (Figure 3.13).

Figure 3.13: Only *cfs1* leaves with lesions accumulate ubiquitinated proteins - Immunodetection of ubiquitinated proteins in
a) leaves of *cfs1* mutants showing lesions and of Col-0, *pCFS1-gCFS1* in *cfs1-2* of the same age.

b) younger *cfs1* mutants whose lesions had yet to be formed and of Col-0 and *pCFS1-gCFS1* in *cfs1-2* plants of the same age.

c) younger *cfs1* mutants whose lesions had yet to be formed and of Col-0, *cfs1 elch*, *elch*, *Ws-2* and i^3 of the same age.

Anti-cFBPase served as a loading control. All experiments were performed with four biological replicates (Figures I.1 to I.3).

In *cfs1* leaves showing lesions, a marked accumulation of ubiquitinated proteins was observed in all samples when compared to wild-type and the complementation lines (*pCFS1-gCFS1* in *cfs1-2*) (Figure 3.13a). In younger *cfs1* plants, however, the level of ubiquitinated proteins detected was comparable to that in wild-type and in the complementation lines (Figure 3.13b), and no

obvious change in the accumulation of ubiquitinated proteins in *cfs1-2 elch* was observed in comparison to *elch* (Figure 3.13c).

3.3.6 *cfs1* mutants accumulate autophagosomes during their lifespan

Because *cfs1* mutants only accumulated ubiquitinated proteins after cell death had already occurred (Figure 3.13a and b) and *cfs1-2 elch* did not accumulate ubiquitinated proteins beyond that of *elch* (Figure 3.13c), I inferred that the accumulation of ubiquitinated proteins in *cfs1* leaves with lesions (Figures 3.13a) is a consequence of cell death rather than a deficiency in the ESCRT-complex function.

Alternative to the insufficiency of an ESCRT-mediated ubiquitinated proteins degradation, Munch et al. (2014) have proposed that deficiencies in autophagy could also lead to an accumulation of ubiquitinated proteins and eventually uncontrolled cell death. For this reason, autophagy malfunction in *cfs1* mutants was investigated by immunoblotting against an autophagosomal membrane marker, AUTOPHAGY-RELATED 8A (ATG8a) (Thompson et al., 2005; Bassham, 2015) and a selective autophagy substrate, NEXT TO BRCA1 GENE 1 (NBR1) (Svenning et al., 2011).

When compared to wild-type, mature *cfs1* leaves showing lesions showed a drastic accumulation of ATG8a and NBR1, ranging from 5 to 45 fold from 0.6 to 23 fold, respectively. In the complemented lines (*pCFS1-gCFS1* in *cfs1-2*), the level of accumulation was reduced to 1.7 - 2.3 fold and to 0.2 - 17 fold for ATG8a and NBR1, respectively (Figure 3.14a,b). To exclude the possibility that accumulation of ATG8a and NBR1 in mature plants resulted from a higher number of dead cells in *cfs1* than in wild-type, I also checked the level of ATG8a and NBR1 accumulation in growing plants without lesions (14-days old) and in young seedlings (7-days old).

In 14-days old *cfs1* mutants, the detected level of ATG8a and NBR1 was 1.7 - 8.1 fold and 0.2 - 4.2 fold in compared to wild-type of the same age, respectively, which were higher than that of the complemented lines of the same age (Figure 3.14c-d). In young seedlings, the level of ATG8a and NBR1 varied

3. RESULTS

Figure 3.14: *cfs1* mutants accumulate autophagosomes during their lifespan - Immunodetection of autophagosomes with anti-ATG8 and anti-NBR1.

(Description continues in page 60)

3.3 *CFS1* function in ESCRT-related trafficking

from 0.96 -14 fold and 0.7 - 6.1 fold when compared to wild-type, respectively. In the complemented lines of the same age, the level of ATG8a and NBR1 accumulation was reduced to 0.49 - 2.96 fold and 0.29 - 2.2 fold, respectively when compared to Col-0 (Figure 3.14e-f). Altogether, this demonstrates that the lack of functional *CFS1* causes an accumulation of autophagosomal components associated with ATG8a and in most cases, NBR1. This accumulation occurs at the early stage of the plant life and becomes more obvious as the plants age.

Under an optimal condition, autophagy transpires at a low level to facilitate basal autophagy activity (Sláviková et al., 2005). When stress occurs, ATG genes are upregulated to increase the formation of autophagosomes (Pu and Bassham, 2013). In developing autophagosome, ATG8 is modified and decorated (Yoshimoto et al., 2004; Thompson et al., 2005; Li and Vierstra, 2012). Mature ATG8-decorated autophagosomes are then transported to the vacuole for degradation (Li and Vierstra, 2012). For this reason, an increased ATG8a accumulation in *cfs1* could point to either a misregulation of basal autophagy or to an incomplete autophagosome formation or degradation.

Arrowhead denotes the band selected for calculation.

3. RESULTS

3.3.6.1 No misregulation of *ATG8* and *NBR1* in *cfs1* mutants

To assess whether basal autophagy is misregulated in *cfs1*, the level of *ATG8* genes and *NBR1* transcripts were assessed in both null (*cfs1-2*) and non-null (*cfs1-3*) alleles in compared to wild-type. In neither null nor non-null *cfs1* alleles was the expression of *ATG8* genes or *NBR1* significantly different from that of Col-0 (Figure 3.15 and Appendix K). This indicates a normal regulation of *ATG8* genes and *NBR1*.

Figure 3.15: **No misregulation of *ATG8* genes or *NBR1* in *cfs1*** - Transcript levels of *ATG8* genes and *NBR1* in *cfs1-2* and *cfs1-3* leaves showing lesions were similar to that of Col-0. The expression levels were normalized to *EF1α* and calibrated to Col-0 of the same age. Y-axis is plotted in log2 scale. Error bars represent standard error. Fold change and statistical tests are shown in Appendix K.

3.3.6.2 No misregulation of ER-stress marker genes in *cfs1* mutants

In addition to ATG-induced autophagosome formation (Li and Vierstra, 2012), autophagosomes could also be induced under ER-stress (Pu and Bassham, 2013), or vice versa (Munch et al., 2014). To attend to this possibility, I checked if *cfs1* mutants are under ER-stress by comparing the level unfolded protein

3.3 CFS1 function in ESCRT-related trafficking

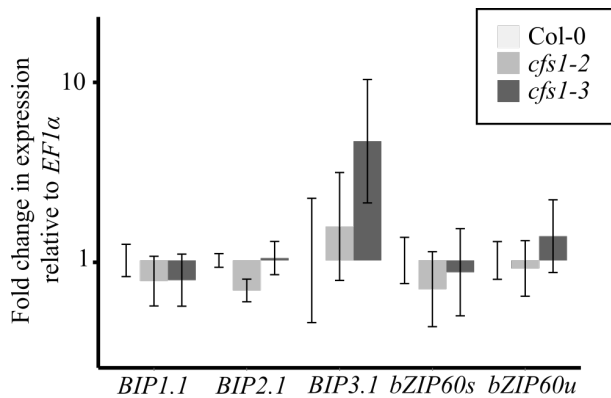

Figure 3.16: **No upregulation of ER-stress marker genes in *cfs1*** - Comparative transcript levels of ER-stress marker genes, *BIP1.1*, *BIP2.1*, *BIP3.1* and *bZIP60* spliced and unspliced variants (*bZIP60s* and *bZIP60u*, respectively) in *cfs1-2* and *cfs1-3* leaves showing lesions to Col-0 of the same age.

Y-axis is plotted in log₁₀ scale. Error bars represent standard error. Fold change of each marker genes and statistical tests are shown in Appendix L.

responses (UPR)-related genes, *LUMINAL BINDING PROTEIN 1.1* (*BIP1.1*), *LUMINAL BINDING PROTEIN 2.1* (*BIP2.1*), and *LUMINAL BINDING PROTEIN 3.1* (*BIP3.1*) that are up-regulated during ER-stress and the level of *BASIC REGION/LEUCINE ZIPPER MOTIF 60* (*bZIP60*) that is spliced to activate the up-regulation of UPR-related genes (Liu et al., 2012; Pu and Bassham, 2013). In both null and non-null alleles of *cfs1*, no significant difference in the transcript levels of these genes was observed when compared to wild-type (Figure 3.16 and Appendix L).

3.3.6.3 Autophagosomes are formed in *cfs1-2*

The usual transcript levels of *ATG8* genes, *NBR1* and ER-stress markers genes in *cfs1* mutants demonstrate that autophagosome accumulation in *cfs1* is not due to misregulation of basal autophagy (Figure 3.15) or higher ER-stress (Figure 3.16). Hence, only defective autophagosome formation or degradation remain as a probable cause of autophagosome accumulation in *cfs1* mutants. Defective autophagosome formation can be translated into failure to form ATG8-punctated structures after induction (Sláviková et al., 2005) and lower tolerance to nutrient starvation (Doelling et al., 2002; Thompson et al., 2005).

When YFP-ATG8a was transiently expressed, YFP signals were present in cytosolic form and dot-like structures in both Col-0 and *cfs1-2* (Figure 3.17a).

3. RESULTS

Figure 3.17: **Autophagosomes can be initiated in *cfs1* mutant** - Autophagosomes formation in Col-0 and *cfs1-2* mutant was initiated by **a)** transient expression of YFP-ATG8a in Col-0 and *cfs1-2*. The number of punctated structures (Tables M.1 and M.2) is summarized in the boxplot in **b)**. Scale bar: 25 μ m. Crosses indicate the average number of punctated structure. Dots indicate outliers. Three asterisks indicate a significant difference at $p \leq 0.001$ level. **c)** 10 days-carbon and nitrogen starvation subjected to 7-days old Col-0 and *cfs1* seedlings. Scale bar: 1cm.

The average number of punctated YFP-ATG8 structures in *cfs1-2* was significantly more than in Col-0 ($p = 0.0005894$, Figure 3.17b; Statistical test is shown in Appendix M). On a phenotypic level, no obvious difference was observed when 7-days old wild-type and *cfs1* seedlings were starved from nitrogen and carbon source for 10 days (Figure 3.17c). Both approaches substantiate a normal autophagosome formation in *cfs1*. Greater number of YFP-ATG8a punctated structure in *cfs1-2* suggests, instead, a faulty autophagosome degradation.

3.3.6.4 Autophagosome accumulation in *cfs1-2* is independent of *EDS1* or *ELCH* function

The accumulation of autophagosomes in *cfs1-2* mutants and the lack thereof in the complemented lines (Figure 3.14) propose that it could be the cause of HR-cell death seen in *cfs1-2*. As it has been demonstrated that autophagosomes accumulate following infection by *Pseudomonas syringae* pv. tomato DC3000 (*PstDC3000*) *AvrRps4* in an *EDS1*-dependent manner (Hofius et al., 2009), it is interesting to see if autophagosome accumulation in *cfs1* mutants would also rely on a functional *EDS1*.

Both growing *cfs1* and *cfs1-2 eds1-2* plants accumulated 2.35 -3.77 fold and 1.99-4.25 fold of ATG8a in comparison to wild-type, respectively. In *eds1-2* mutants of the same age, the accumulation was 1.18 - 2.98 in comparison to wild-type. The level of NBR1 accumulation was 1.01-2.06 fold, 1.22-2.40 fold and 0.81-1.14 fold in compared to wild-type for *cfs1-2*, *cfs1-2 eds1-2* and *eds1-2*, respectively (Figure 3.18a, b). Altogether, this shows that autophagosome accumulation in *cfs1-2* is, unlike its cell death phenotype, independent of *EDS1* function.

Since cell death in *cfs1-2 elch* progressed slower than in *cfs1-2* (Figure 3.12), it seems likely that the lack of a functional *ELCH* may affect autophagosome accumulation in *cfs1-2*. To tackle this, 14 days old plants (approximately 20 DAS, without an appearance of lesions in *cfs1-2* and *cfs1-2 elch*) were detected for ATG8a and NBR1 accumulation. The accumulation of ATG8 was 2.09 -4.59 fold, 1.99 -5.38 fold in comparison to Col-0 in *cfs1-2* and *cfs1-2 elch*, respectively and 0.78 - 4.27 fold in comparison to Ws-2 in *elch*. As for NBR1, *cfs1-2* and *cfs1-2 elch* accumulated 1.31-2.19 fold and 1.09-2.30 fold in comparison to Col-0, respectively and 0.88-6.29 fold in comparison to Ws-2 in *elch* (Figure 3.18c,d). All in all, this shows that the lack of functional *ELCH* does not drastically affect autophagosome accumulation in *cfs1-2*.

3. RESULTS

Figure 3.18: Neither lack of *EDS1* nor *ELCH* function affect autophagosomes accumulation in *cfs1* - Immunodetection of autophagosomes with anti-ATG8 and anti-NBR1 in

a) 14-days old Col-0, *eds1-2*, *cfs1-2* and *cfs1-2 eds1-2*. The intensities of detected anti-ATG8a and anti-NBR1 bands of all four biological replicates (Figures J.16 to J.19) are depicted in **b**).

c) 14-days old Col-0, *cfs1*, *cfs1 elch*, *elch*, *Ws-2* and *i³*. The intensities of detected anti-ATG8a and anti-NBR1 bands of all four biological replicates (Figures J.12 to J.15) are depicted in **d**).

Anti-cFBPase served as a loading control.

4. Discussions

CFS1 is a plant specific actin- and PI3P-binding protein that interacts with the ESCRT-I component, ELCH (Herberth, 2012). The mutant of this gene mimics lesion formation (Sutipatanasomboon, 2012). The characterization of *cfs1* phenotype reveals that it displays a mild autoimmune symptoms (Figures 3.2, 3.3 and 3.5) and starts to accumulate autophagosomes from the seedlings stage (Figure 3.14). Genetic analyses have demonstrated that HR-cell death in *cfs1* is independent of a functional ESCRT-I component (Figure 3.12) but requires a functional EDS1-induced ETI (Figure 3.6). Although cell death phenotype is lost in *cfs1-2 eds1-2* (Figure 3.6), the mutant still accumulates autophagosomes (Figure 3.18), indicating a separate contribution of *CFS1* to autophagosomes accumulation and of *EDS1* to HR-cell death. Correspondingly, these findings raise the question of how HR-cell death is triggered in *cfs1*; how does *CFS1* contribute to autophagy; and how these processes are connected to the ESCRT-complex related trafficking.

4.1 The cause of death in *cfs1*

Autophagy is a conserved degradative mechanism that sequesters cellular constituents and damaged organelles and delivers them to the vacuole or lysosomes for degradation (Klionsky and Emr, 2000). Under an optimal condition in plants, autophagy activity is basal to maintain cellular homeostasis (Sláviková et al., 2005). Under stress condition, the autophagy genes are transcriptionally up-regulated (Liu and Bassham, 2010; Liu et al., 2012) to increase autophagy degradation that accommodates cellular responses for homeostasis maintenance (Li and Vierstra, 2012; Babst and Odorizzi, 2013).

The autophagosome accumulation in *cfs1* started at the early stage and became more obvious as the plants aged (Figure 3.14). Considering the promoter activity that was depleted as the leaf aged (Figure 3.4), the increasing accumu-

4. DISCUSSIONS

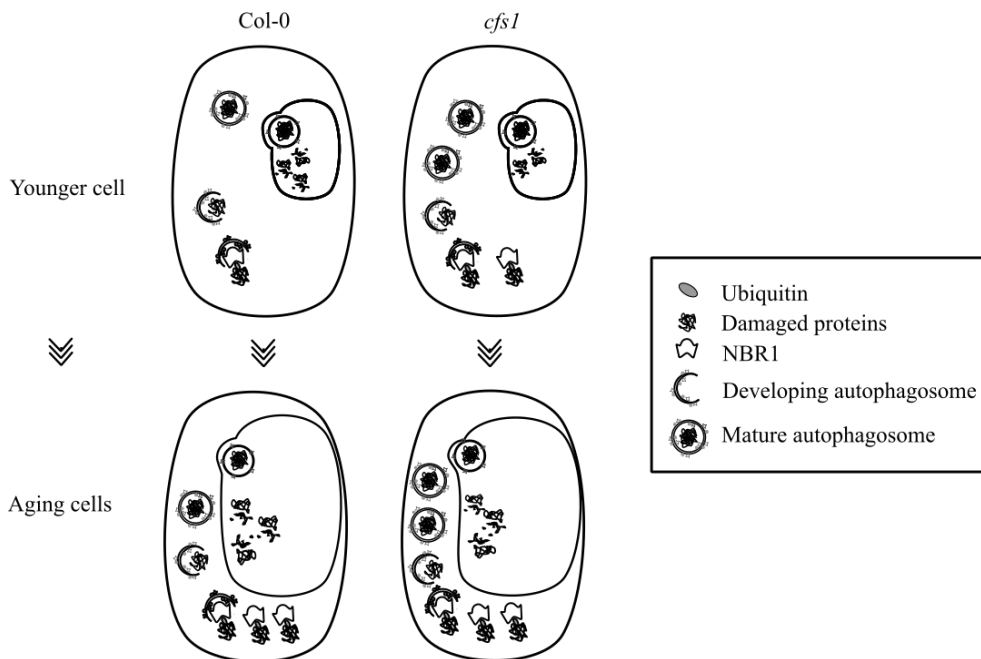

Figure 4.1: **Schematic representation of younger and aging wild-type and *cfs1* palisade cell** - In younger cells, autophagosomes start to accumulate in *cfs1* when compared to wild-type at the same age. As the cell ages, damaged proteins and organelles increase, causing a homeostasis imbalance in *cfs1* due to cumulated autophagosomes from the earlier stage.

lation possibly reflects the cumulating lack of *CFS1* activity (Figure 4.1). In the embryogenesis of *Picea abies*, down-regulation of autophagic components disrupts vacuolar cell death in suspensor cells and causes premature necrosis cell death (Minina et al., 2013). In a similar manner, a hindered autophagy activity in *cfs1* can be translated into the appearance of HR-cell death (Figure 3.2). In this regard, cell death in *cfs1* is a cumulative rather than a first-hand occurrence and is likely precipitated by the accumulation of autophagosomes. At the earlier stage, the effect of autophagosome accumulation in *cfs1* to protein homeostasis is probably small and tolerable; however, as the plant ages and is constantly subjected to more stress (Figure 4.1; Coll et al., 2014), the little disturbance cumulates and becomes a crucial factor that breaches the point of no return for homeostasis perturbation. The propagation aspect of *cfs1* phenotype can be explained by the cellular threshold for protein homeostasis that is breached in the older cells before younger cells.

4.1.1 How *CFS1* disruption falsely triggers ETI

Effector-triggered immunity (ETI) is a defensive strategy plants have developed against adapted pathogens that have infected the plants (Wiermer et al., 2005). The centrality of ETI revolves around the plants ability to perceive and distinguish the presence of pathogenic molecules in the cells (Coll et al., 2011). This perception activates downstream defense responses that are mediated by EDS1 or NDR1 (Wiermer et al., 2005). In case of EDS1-mediated ETI, the signal comes from the binding of TIR-NB-LRR *R*-protein to virulent effectors (Aarts et al., 1998). Alternatively, *R*-protein can indirectly perceive pathogen presence by sensing a modification of its binding partner that originates from pathogen effector (Dodds and Rathjen, 2010). This is reflected in several autoimmune mutants whose gene functions are not directly involved in HR-cell death but have been proposed to be targeted by pathogen effectors (Palma et al., 2010; Bruggeman et al., 2015). For example ACD11, another LMM in *CFS1* protein interaction network, is a ceramide-1-phosphate transfer protein that regulates the level of cellular phytoceramides (Simanshu et al., 2014) and also interacts with TIR-NB-LRR-like *R* protein, LAZARUS5 (LAZ5) (Palma et al., 2010). It has been proposed that in *acd11*, the disturbance in ceramide level causes an imbalance in death-promoting phytoceramides that may mimic a non-self environment similar to when pathogen effectors modify ACD11 (Munch et al., 2015).

Downstream signaling of ETI results in several cellular responses. One of them is to induce autophagy for the execution of HR-cell death (Hofius et al., 2011; Coll et al., 2014). It has been demonstrated in *Arabidopsis* infected with *PstDC3000 AvrRpm1* and *AvrRpm4* that autophagosomes were initiated in concert with a global transcriptional defense responses mediated by EDS1 (Hofius et al., 2009). In younger *autophagy-related genes defecient (atg)* mutants, HR-cell death was suppressed following *PstDC3000 AvrRpm1* and *AvrRpm4* infection (Yoshimoto et al., 2009; Hofius et al., 2009; Coll et al., 2014). This effect, however, disappeared when the *atg* plants became older and worsened as runaway cell death was developed a few days after infection (Yoshimoto et al., 2009). Nevertheless, HR-cell death suppression was restored again when ER stress

4. DISCUSSIONS

(Munch et al., 2014) or SA-accumulation (Yoshimoto et al., 2009) was relieved. The phenotype in older plants suggests that the accumulated cellular garbage in older *atg* mutants is so overwhelming that it masks the autophagy role in HR-cell death (Hofius et al., 2011; Coll et al., 2014) and also hints at the feedback amplification loop through homeostasis perturbation and SA-signaling (Zhou et al., 2014a).

The requirement of a functional EDS1 and ETI for *cfs1* HR-cell death (Figure 3.6) places *CFS1* at the same functional level as TIR-NB-LRRs, which trigger *EDS1*-mediated ETI following pathogen perception (Wiermer et al., 2005). The detection of autophagosomes in the HR-cell death suppressed *cfs1-2 eds1-2* (Figure 3.18a) separates the cell death signaling from autophagosome accumulation and suggests that it triggers *EDS1*-signaling. By drawing the same rationale as in *acd11*, the cumulated homeostasis perturbation in *cfs1* might be perceived as a non-self environment that falsely invokes HR-cell death. Unlike *acd11*, however, no known NB-LRR protein has been found in the *CFS1*-interactor proteomic screen (Personal communication S Herberth) nor does *cfs1* phenotype require the presence of SA (Figure 3.7). These suggest that autophagosome accumulation in *cfs1* may trigger an *EDS1*-ETI feedback mechanism through homeostasis perturbation that is proposed to function in parallel to SA-induced SAR (Bartsch et al., 2006; Breitenbach et al., 2014). In this case, ETI induction in *cfs1* may be suppressed by up-regulating another the degradation pathway and may be unspecific to *EDS1* because *NDR1* also partially contributes to *PstDC3000 AvrRpm1*-induced HR (Aarts et al., 1998) that partly relies on autophagy machinery for HR-cell death execution (Coll et al., 2014).

4.2 How does *CFS1* contribute to autophagy?

Several lines of evidence from this study indicate that the disruption of *CFS1* interferes with autophagosome degradation. First, the level of ER and oxidative-stress marker genes, which can induce autophagy, (Xiong et al., 2007; Munch et al., 2014) were comparable to wild-type (Figures 3.8 and 3.16). Second, the transcript levels of autophagosome component genes and its selective substrate, *NBR1* in *cfs1* were similar to wild-type (Figure 3.15). Lastly, *ATG8*-

4.2 How does CFS1 contribute to autophagy?

associated punctated structures were formed in *cfs1*, and the nutrient-starvation induced autophagy degradation was functional to a certain degree (Figure 3.17). Therefore, autophagy interference in *cfs1* is not in the initiation of or degradation by autophagy per se but in the degradation of mature autophagosomes (Figure 4.1).

4.2.1 CFS1 could contribute to autophagy via its PI3P and actin binding property

In developing autophagosomes, PI3P is adhered, and the residing phosphatidylethanolamine (PE) is attached to ATG8, providing a unique mark for a developing phagophore and a docking platform for ATG8-interacting proteins (Li and Vierstra, 2012). This that drives autophagosome maturation, selective cargo recruitment and delivery to vacuole (Johansen and Lamark, 2011). Several PI3P-binding proteins have been reported to aid autophagosome maturation. For example, a PI3P binding protein in mammals, double FYVE domain-containing protein 1 (DFCP1) has been shown to translocate from the ER or TGN after nutrient starvation induction to the growing ATG8-punctated structures (Burman and Ktistakis, 2010). PI3P and ATG8-PE on autophagosomal membrane can also be recognized by a class of conserved FYVE and CC domain-containing protein (FYCO) that interacts with ATG8 (Li and Vierstra, 2012). In mammalian cell, FYCO1 transports autophagosomes to vacuole via microtubule plus end-directed movement. FYCO1 depletion is mirrored by an accumulation of ATG8-punctated structure (Pankiv et al., 2010), similar to that in *cfs1-2* (Figure 3.17).

These two examples, together with a report of the actin influence on autophagosome maturation (Aguilera et al., 2012) suggest that a possible autophagic disturbance in *cfs1* likely results from the lack of PI3P and actin-binding that is mediated by the FYVE and/or SYLF domain of the protein. The YAB/SYLF domain functions in the inward movement of the endocytotic cargo in budding yeast (Robertson et al., 2009) and contributes to the interaction with Dedicator of cytokinesis 4 (Dock4) that promotes cancer cell migration (Kobayashi et al., 2014). Interestingly, CFS2 interacts with its only homolog CFS1 (Herberth, 2012), whose interaction with ATG8 has been reported

4. DISCUSSIONS

in the BioGRID database (Stark et al., 2006). In a transient expression assay, CFS2 localization was largely cytoplasmic with low numbers of dots (J Müller BSc thesis, 2014), similar to the the localization of ATG8 under a non-induced condition (Bassham, 2015). In the light of a revealed CFS1 connection to autophagosomes, the localization of CFS1, CFS2 and ELCH should be examined under normal and stress-induced condition with an emphasis on how they are related to ATG8. The interaction between CFS1, CFS2 and ATG8 should also be tested, and the phenotype in a null *cfs2* should be analyzed.

4.2.2 CFS1 could contribute to autophagosome degradation from its interaction with the ESCRT-I component

The ESCRT-complex has been shown to be involved in autophagy initiation, maturation and degradation in budding yeast, *Caenorhabditis elegans*, *Drosophila melanogaster* and various types of mammalian cells (Metcalf and Isaacs, 2010). Therefore, it is foreseeable that CFS1 contribution to autophagy is also through its interaction with the ESCRT-complex component. Although *elch* and *i³* showed the same level of autophagosomes accumulation as in wild-type (Figure 3.18), there have been several reports on the accumulation of autophagosomes from organisms that only have one gene for ELCH/VPS23 and VPS28 (Manil-Segalén et al., 2012; Teis et al., 2009), suggesting the effect in *elch* and *i³* reported here might be concealed by the other functional ESCRT-I components.

Nevertheless, autophagosomes accumulation was reported in *free1*, a plant-specific ESCRT-I component (Gao et al., 2015). FREE1 was shown to regulate ILV formation into the MVB (Gao et al., 2014). When induced by SA agonist, *free1* accumulated higher number of autophagosomes co-localizing with MVBs although less autophagosomes were found in the vacuole. This can be inferred that in plants, apart from the direct delivery of autophagosomes to vacuole, they can also fuse to late endosomes or MVB beforehand (Gao et al., 2015), forming an *amphisome* as reported in budding yeast and various types of mammalian cell (Metcalf and Isaacs, 2010; Manil-Segalén et al., 2012). This concept is supported by a similar phenotype in the later ESCRT components: ESCRT-III components, CHMP1A and CHMP1B (Spitzer et al., 2015)

4.2 How does CFS1 contribute to autophagy?

and an accessory ESCRT-III subunit, ASSOCIATED MOLECULE WITH THE SH3 DOMAIN OF STAM 1 (AMSH1) (Katsiarimpa et al., 2013). Double mutant of ESCRT-III subunits, *chmp1a chmp1b* delivered lesser plastids-containing autophagosome to vacuole (Spitzer et al., 2015). Similarly, under nutrient-starved condition, *amsh1* accumulated autophagosomes, but lesser autophagosomes were detected in the vacuoles of *amsh1* than that of wild-type (Katsiarimpa et al., 2013).

Figure 4.2: **Proposed model of how CFS1 contributes to autophagosome degradation** - CFS1 can contribute to autophagosome degradation through its interaction with CFS2 and ELCH/ESCRT-I component. Together with CFS2, CFS1 sequesters mature autophagosome to the MVB surface. The ESCRT-I components then initiates the fusion of MVB and autophagosome, forming an amphisome.

The accumulation of autophagosomes in *free1*, *chmp1a chmp1b* and *amsh1* indicate that the ESCRT-complex mediates amphisome formation and/or their subsequent delivery to vacuole. Taken the sequential nature of the ESCRT-complex action together with the specificity of CFS1 interaction to ELCH (Herberth, 2012), it is proposed here that CFS1 together with CFS2 function in bridging a mature autophagosome to a MVB where the ESCRT-complex resides to facilitate amphisome formation (Figure 4.2).

4. DISCUSSIONS

4.3 Concluding remarks

The findings that *CFS1* deficiency interferes with autophagosome degradation (Figure 3.14) and affects ETI-induced HR-cell death connect the ESCRT-complex to autophagosome degradation and emphasize the importance of protein homeostasis maintenance in the cell. This is demonstrated in the recent proteomic analysis in nutrient-starved budding yeasts that reveals a coordinated action of MVB and autophagy-mediated degradation. In the early phase of starvation, MVB action provides building blocks for autophagy degradation by selectively degrading transmembrane protein (Müller et al., 2015). Therefore, it is not too far-fetched to speculate that such coordination between the two pathways also exist in plants, and that they are crucial in the developmental processes and adaptation to stress.

Intriguingly, other than autophagy that emerges from this study, *CFS1* has been shown to be involved in ubiquitin/26S proteasome system (UPS) through its interaction with XBAT35 and CHIP - both an E3 ligase (Ulbricht, 2011). CHIP interacts with molecular chaperones to ubiquitinate misfolded proteins for degradation by UPS (Lee et al., 2009) in an anti-proteotoxic pathways complementary to NBR1 (Zhou et al., 2014b). NBR1 targets ubiquitinated protein aggregates (Kirkin et al., 2009; Zhou et al., 2013) and act as a substrate for selective autophagy degradation (Svenning et al., 2011). It has been demonstrated that prolonged heat stress increases misfolded proteins. Due to a limited capacity of UPS, these increased misfolded proteins aggregate and are targeted by NBR1 for selective autophagy degradation (Figure 4.3; Zhou et al., 2014b; Kirkin et al., 2009). *CFS1* interaction with CHIP and XBAT35 suggest an involvement of *CFS1* in modulating UPS and autophagy-mediated degradation, also known as chaperone-assisted selective autophagy (CASA) (Johansen and Lamark, 2011), which has not been dissected in plants (Figure 4.3; Li and Vierstra, 2012).

Alternatively, it has been recently demonstrated in fission yeast (*Schizosaccharomyces pombe*) that the ESCRT-complex directly sorts NBR1-bound cargo into the MVB (Liu et al., 2015). Thus, it could be speculated that *CFS1* would be involved in this process if similar pathway existed in plants (Figure 4.3).

Figure 4.3: **Functional landscape of CFS1 in the endomembrane system** - Misfolded proteins are recognized and ubiquitinated by CHIP and molecular chaperones for the degradation by UPS. Misfolded proteins aggregate when subjected to prolonged stress. Protein aggregates are ubiquitinated and recognized by NBR1 that acts as a substrate for selective autophagy. Together with CFS2 and the ESCRT-complex, it is proposed that CFS1 functions in sequestering mature autophagosome to MVB where amphisome is formed before subsequent delivery to vacuole. Whether CFS1 interaction with CHIP facilitates misfolded protein degradation via CASA or ESCRT-mediated MVB-pathway remains to be explored.

All things considered, this study provides a functional landscape of *CFS1* in the ESCRT-complex related protein trafficking (Figure 4.3). *CFS1* functions, possibly together with *CFS2*, in sequestering mature autophagosomes to late endosomes where the ESCRT-complex resides. This interaction is crucial for a proper degradation of autophagosomes. Considering that *CFS1* also interacts with other two E3 ligases, it is feasible that *CFS1* also influences CASA. To further explore this possibility, the function of *CFS1* in relation to autophagy, CHIP and XBAT35, as well as *CFS2* to ATG8 should be investigated. By the same token, the effect of up- or down-regulating UPS and MVB-pathways on autophagosomes degradation and HR-cell death phenotype in *chs1* should also be examined.

Appendices

Appendix A Statistical analysis of *pCFS1-gCFS1* in *cfs1-2* plants

Pearson's χ^2 test of independence was performed using *prop.test* function without continuity correction.

For **line 1**:

two-sided test:

$\chi^2 = 0.18125$, $df = 1$, $p\text{-value} = 0.6703$

95 percent confidence interval: -0.5191644, 0.3524977

sample estimates: prop 1 = 0.1666667; prop 2 = 0.2500000

For **line 2**:

two-sided test:

$\chi^2 = 1.8887$, $df = 1$, $p\text{-value} = 0.1693$

95 percent confidence interval: -0.6183967, 0.2408456

sample estimates: prop 1 = 0.06122449; prop 2 = 0.25000000

For **line 3**:

two-sided test:

$\chi^2 = 0.053968$, $df = 1$, $p\text{-value} = 0.8163$

95 percent confidence interval: -0.497835, 0.397835

sample estimates: prop 1 = 0.20; prop 2 = 0.25

For **line 4**:

two-sided test:

$\chi^2 = 0.0077061$, $df = 1$, $p\text{-value} = 0.93$

95 percent confidence interval: -0.4587557, 0.4202941

sample estimates: prop 1 = 0.2307692; prop 2 = 0.2500000

All statistical analyses were performed using the functions described in Appendix C. Function *kruskal.test* was used for Kruskal-Wallis rank sum test. ΔC_t values were subjected to statistical test as follows:

For *MC1*:

Shapiro-Wilk normality test: normality accepted

(W = 0.85064, p-value = 0.07573)

ANOVA:

	Df	Sum Sq	Mean Sq	F Value	Pr(> F)
genotype	2	0.3447	0.17237	1.873	0.233
Residuals	6	0.5521	0.092		

Signif. codes: 0 *** 0.001 ** 0.01 * 0.05 . 0.1 1

For *PR2*:

Shapiro-Wilk normality test: normality rejected

(W = 0.75987, p-value = 0.007054)

Kruskal-Wallis rank sum test:

Kruskal-Wallis chi-squared = 0.2735, df = 2, p-value = 0.8722

For *RNS3*:

Shapiro-Wilk normality test: normality rejected

(W = 0.81643, p-value = 0.0314)

Kruskal-Wallis rank sum test:

Kruskal-Wallis chi-squared = 2.4615, df = 2, p-value = 0.2921

For *BFN1*:

Shapiro-Wilk normality test: normality accepted

(W = 0.95104, p-value = 0.7015)

ANOVA:

	Df	Sum Sq	Mean Sq	F Value	Pr(> F)
genotype	2	4.504	2.252	0.808	0.489
Residuals	6	16.732	2.789		

Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

For *CAN1*:

Shapiro-Wilk normality test: normality accepted

(W = 0.91294, p-value = 0.337)

ANOVA:

	Df	Sum Sq	Mean Sq	F Value	Pr(> F)
genotype	2	0.3296	0.1648	0.496	0.632
Residuals	6	1.9917	0.3319		

Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

For *GLY3*:

Shapiro-Wilk normality test: normality rejected

(W = 0.82849, p-value = 0.04295)

Kruskal-Wallis rank sum test:

Kruskal-Wallis chi-squared = 2.4615, df = 2, p-value = 0.2921

For *FES1A*:

Shapiro-Wilk normality test: normality rejected

(W = 0.81127, p-value = 0.02745)

Kruskal-Wallis rank sum test:

Kruskal-Wallis chi-squared = 7.3846, df = 2, p-value = 0.02491

For *UGT87E2*:

Shapiro-Wilk normality test: normality rejected

(W = 0.65775, p-value = 0.0004549)

Kruskal-Wallis rank sum test:

Kruskal-Wallis chi-squared = 1.1852, df = 2, p-value = 0.5529

E Analysis of cell death executioner and oxidative stress marker genes

For *RD21*:

Shapiro-Wilk normality test: normality rejected

(W = 0.72058, p-value = 0.002467)

Kruskal-Wallis rank sum test:

Kruskal-Wallis chi-squared = 0.82051, df = 2, p-value = 0.6635

Fold change in relative to Col-0 and its corresponding minimum and maximum fold change is listed in Table E.2

	Σ	1733	0	1733	0.000	14	0	14

%*elch*: Percentage of *elch* trichome number to total trichome number

N_{WT}: Number of leaves showing wild-type trichome

N_{*elch*}: Number of leaves showing *elch* trichome

N_{all}: Number of all leaves counted

Fisher's exact test was performed using *fisher.test* function. The results were as follows:

For **leaf number 3:**

two-sided test:

p-value = 0.0009012

sample estimates: odds ratio 0.2039913

Test if *elch* trichome in *cfs1-2 elch* is less than in *elch*:

p-value = 0.0006384

sample estimates: odds ratio 0.2039913

For **leaf number 4:**

two-sided test:

p-value = 0.06037

sample estimates: odds ratio 0.4933059

Test if *elch* trichome in *cfs1-2 elch* is less than in *elch*:

p-value = 0.03176

sample estimates: odds ratio 0.4933059

For **both leaf number:**

two-sided test:

p-value = 3.666e-05

sample estimates: odds ratio 0.3212671

Test if *elch* trichome in *cfs1-2 elch* is less than in *elch*:

p-value = 2.428e-05

sample estimates: odds ratio 0.3212671

Pearson's χ^2 test of independence was performed using *prop.test* function without continuity correction.

For **leaf number 3:**

two-sided test:

$\chi^2 = 10.742$, $df = 1$, p-value = 0.001047

Test if *elch* trichome in *elch* is greater than in *elch*:

$\chi^2 = 10.742$, $df = 1$, p-value = 0.001047

For leaf number 3:

two-sided test:

$$\chi^2 = 10.742, df = 1, p\text{-value} = 0.001047$$

Test if *elch* trichome in *elch* is greater than in *elch*:

$$\chi^2 = 10.742, df = 1, p\text{-value} = 0.0005237$$

For leaf number 4:

two-sided test:

$$\chi^2 = 4.1389, df = 1, p\text{-value} = 0.041911$$

Test if *elch* trichome in *elch* is greater than in *elch*:

$$\chi^2 = 4.1389, df = 1, p\text{-value} = 0.02095$$

For both leaf number:

two-sided test:

$$\chi^2 = 13.628, df = 1, p\text{-value} = 0.0002228$$

Test if *elch* trichome in *elch* is greater than in *elch*:

$$\chi^2 = 13.628, df = 1, p\text{-value} = 0.0001114$$

Appendix I Accumulation of ubiquitinated proteins

Figure I.1: **Accumulation of ubiquitinated proteins in mature plants** - Crude extract of *cfs1* leaves showing lesions and the other of the same age were probed with anti-Ub(P4D1) to detect accumulation of ubiquitinated proteins. Anti-cFBPase was used as a loading control. The experiments was repeated with four biological replicates (a-d)

Figure I.2: **Accumulation of ubiquitinated proteins in growing plants** - Crude extract from growing plants without lesions was probed with anti-Ub(P4D1) to detect accumulation of ubiquitinated proteins. Anti-cFBPase was used as a loading control. The experiment was repeated with four biological replicates (a-d)

Figure I.3: **Accumulation of ubiquitinated proteins in *cfs1-2* and *cfs1-2 elch*** - Crude extract from *cfs1-2* and *cfs1-2 elch* leaves without lesions were probed with anti-Ub(P4D1) to detect accumulation of ubiquitinated proteins. Anti-cFBPase was used as a loading control. The experiments was repeated with four biological replicates (a-d)

Appendix J Accumulation of autophagosomes

For the calculation purpose, samples probed with anti-cFBPase were used as a loading control and were relatively adjusted (Relative density) by comparing the difference of band intensity (Area) between samples loaded and blotted onto the same membrane. %Peak referred to the transformed value of Area as percentage obtained from Fiji/ImageJ. The extent of ATG8a and NBR1 accumulation (Adjusted density, AD) was calculated by dividing the %Peak adjusted with the relative density of the loading control of the corresponding samples. Relative ATG8a and NBR1 accumulation (Relative AD) was calculated by dividing AD with that of the corresponding ecotype background.

For mature plants, samples were grown in soil for 24-30 days (approximately 8-leaf stage), and leaves showing lesion were collected. The experiments were repeated with four biological replicates (Figures J.1 to J.4).

For growing plants, samples were grown in soil for 14-16 days and collected at 4-leaf stage. The experiment was repeated with four biological replicates (Figures J.5 to J.8).

Samples used for young seedlings were grown in half-strength MS medium plates for 7-10 days. This experiment was repeated with three biological replicates (Figures J.9 to J.11).

For *escrt* mutant and *cfs1-2 elch* double mutants, plants were grown on soil for approximately 14 days and collected at 4-leaf stage. The extent of accumulation in *elch* was in relative to *Ws-2* and in i^3 relative to *elch*. This experiment was repeated with four biological replicates (Figures J.12 to J.15).

For *cfs1-2* mutant and *cfs1-2 eds1-2* double mutants, plants were grown on soil and collected at 4-leaf stage. This experiment was repeated with four biological replicates (Figures J.16 to J.19).

J Accumulation of autophagosomes

Figure J.1: Accumulation of autophagosomes in mature plants from leaves showing lesions: the first biological replicates - Crude extract was probed with a) anti-cFBPase, b) anti-ATG8a and c) anti-NBR1. Arrowhead denotes expected protein size. Filled arrowhead indicates bands used for intensity calculation.

Figure J.2: Accumulation of autophagosomes in mature plants from leaves showing lesions: the second biological replicates - Crude extract was probed with a) anti-cFBPase, b) anti-ATG8a and c) anti-NBR1. Arrowhead denotes expected protein size. Filled arrowhead indicates bands used for intensity calculation.

J Accumulation of autophagosomes

Figure J.3: Accumulation of autophagosomes in mature plants from leaves showing lesions: the third biological replicates - Crude extract was probed with a) anti-cFBPase, b) anti-ATG8a and c) anti-NBR1. Arrowhead denotes expected protein size. Filled arrowhead indicates bands used for intensity calculation.

Figure J.4: Accumulation of autophagosomes in mature plants from leaves showing lesions: the fourth biological replicates - Crude extract was probed with a) anti-cFBPase, b) anti-ATG8a and c) anti-NBR1. Arrowhead denotes expected protein size. Filled arrowhead indicates bands used for intensity calculation.

Figure J.5: Accumulation of autophagosomes in growing plants: the first biological replicates - Crude extract from growing plant was probed with a) anti-cFBPase, b) anti-ATG8a and c) anti-NBR1. Arrowhead denotes expected protein size. Filled arrowhead indicates bands used for intensity calculation.

Figure J.6: Accumulation of autophagosomes in growing plants: the second biological replicates - Crude extract from growing plants was probed with a) anti-cFBPase, b) anti-ATG8a and c) anti-NBR1. Arrowhead denotes expected protein size. Filled arrowhead indicates bands used for intensity calculation.

J Accumulation of autophagosomes

Figure J.7: Accumulation of autophagosomes in growing plants: the third biological replicates - Crude extract from growing plants probed with a) anti-cFBPase, b) anti-ATG8a and c) anti-NBR1. Arrowhead denotes expected protein size. Filled arrowhead indicates bands used for intensity calculation.

Figure J.8: Accumulation of autophagosomes in growing plants: the fourth biological replicates - Crude extract from growing plants probed with a) anti-cFBPase, b) anti-ATG8a and c) anti-NBR1. Arrowhead denotes expected protein size. Filled arrowhead indicates bands used for intensity calculation.

J Accumulation of autophagosomes

Figure J.9: Accumulation of autophagosomes in young seedlings: the first biological replicates - Crude extract from young seedlings probed with **a)** anti-cFBPase, **b)** anti-ATG8a and **c)** anti-NBR1. Arrowhead denotes expected protein size. Filled arrowhead indicates bands used for intensity calculation.

Figure J.10: Accumulation of autophagosomes in young seedlings: the second biological replicates - Crude extract from young seedlings probed with **a)** anti-cFBPase, **b)** anti-ATG8a and **c)** anti-NBR1. Arrowhead denotes expected protein size. Filled arrowhead indicates bands used for intensity calculation.

J Accumulation of autophagosomes

Figure J.11: **Accumulation of autophagosomes in young seedlings: the third biological replicates** - Crude extract from young seedlings probed with **a)** anti-cFBPase, **b)** anti-ATG8a and **c)** anti-NBR1. Arrowhead denotes expected protein size. Filled arrowhead indicates bands used for intensity calculation.

Figure J.12: Accumulation of autophagosomes in *elch* and *cfs1-2 elch* mutants: the first biological replicates - Crude extract was probed with a) anti-cFBPase, b) anti-ATG8a and c) anti-NBR1. Arrowhead denotes expected protein size. Filled arrowhead indicates bands used for intensity calculation.

J Accumulation of autophagosomes

Figure J.13: Accumulation of autophagosomes in *elch* and *cfs1-2 elch*: the second biological replicates - Crude extract was probed with a) anti-cFBPase, b) anti-ATG8a and c) anti-NBR1. Arrowhead denotes expected protein size. Filled arrowhead indicates bands used for intensity calculation.

Figure J.14: Accumulation of autophagosomes in *elch* and *cfs1-2 elch*: the third biological replicates - Crude extract was probed with a) anti-cFBPase, b) anti-ATG8a and c) anti-NBR1. Arrowhead denotes expected protein size. Filled arrowhead indicates bands used for intensity calculation.

J Accumulation of autophagosomes

Figure J.15: Accumulation of autophagosomes in *elch* and *cfs1-2 elch*: the fourth biological replicates - Crude extract was probed with a) anti-cFBPase, b) anti-ATG8a and c) anti-NBR1. Arrowhead denotes expected protein size. Filled arrowhead indicates bands used for intensity calculation.

Figure J.16: **Accumulation of autophagosomes in *cfs1-2* and *cfs1-2 eds1-2* mutants: the first biological replicates** - Crude extract was probed with a) anti-cFBPase, b) anti-ATG8a and c) anti-NBR1. Arrowhead denotes expected protein size. Filled arrowhead indicates bands used for intensity calculation.

J Accumulation of autophagosomes

Figure J.17: Accumulation of autophagosomes in *cfs1-2* and *cfs1-2 eds1-2*: the second biological replicates - Crude extract was probed with a) anti-cFBPase, b) anti-ATG8a and c) anti-NBR1. Arrowhead denotes expected protein size. Filled arrowhead indicates bands used for intensity calculation.

Figure J.18: Accumulation of autophagosomes in *cfs1-2* and *cfs1-2 eds1-2*: the third biological replicates - Crude extract was probed with a) anti-cFBPase, b) anti-ATG8a and c) anti-NBR1. Arrowhead denotes expected protein size. Filled arrowhead indicates bands used for intensity calculation.

J Accumulation of autophagosomes

Figure J.19: Accumulation of autophagosomes in *cfs1-2* and *cfs1-2 eds1-2*: the fourth biological replicates - Crude extract was probed with a) anti-cFBPase, b) anti-ATG8a and c) anti-NBR1. Arrowhead denotes expected protein size. Filled arrowhead indicates bands used for intensity calculation.

Appendix K Analysis of *ATG8* genes and *NBR1* transcripts

Ct values from each technical and biological replicates are listed in Table K.1.

Appendix K.1: Ct values of *EF α 1*, *ATG8* and *NBR1* transcripts

Appendix M Analysis of YPF-ATG8a punctate structure

All Z-slices of the image were combined to generate image showing maximum projection. Images were manually thresholded and then subjected to particle analysis function. Result of the analysis of an individual sample is displayed in Table M.1 and M.2. The number of YFP-ATG8a punctate structure (Count) were used for subsequent statistical analysis.

To test for significant difference between two groups, the data tested for normality using Shapiro-Wilk's test for normality ($W = 0.76276$, $p\text{-value} = 6.889e-09$). As normality was rejected, Wilcoxon rank sum test with continuity correction was applied ($W = 265$, $p\text{-value} = 0.0005894$).

Erklärung

Ich versichere, dass ich die von mir vorgelegte Dissertation selbständig angefertigt, die benutzten Quellen und Hilfsmittel vollständig angegeben und die Stellen der Arbeit einschließlich Tabellen, Karten und Abbildungen, die anderen Werken im Wortlaut oder dem Sinn nach entnommen sind, in jedem Einzelfall als Entlehnung kenntlich gemacht habe; dass diese Dissertation noch keiner anderen Fakultät oder Universität zur Prüfung vorgelegen hat; dass sie abgesehen von unten angegebenen Teilpublikationen noch nicht veröffentlicht worden ist, sowie, dass ich eine solche Veröffentlichung vor Abschluss des Promotionsverfahrens nicht vornehmen werde. Die Bestimmungen der Promotionsordnung sind mir bekannt. Die von mir vorgelegte Dissertation ist von Prof. Dr. Martin Hülskamp betreut worden.

Köln, den 15 October 2015

Lebenslauf

Persönliche Daten

Name: Sutipatanasomboon
Vorname: Arpaporn
Geburtsdatum: 25 Januar 1988
Geburtsort: Bangkok
Staatsangehörigkeit: Thailand
E-mail: asutipat@smail.uni-koeln.de

Ausbildung

Studienverlauf

seit Oktober 2012 Promotionstudium am Botanisches Institut III
Universität zu Köln

Oktober 2010 - September 2012 Master of Science (Biological Sciences)
Universität zu Köln

Juni 2006 - März 2010 Bachelor of Science (Plant Sciences)
with *First Class Honors*
Mahidol University, Thailand

Schulbildung

Juni 2000 - März 2006 Sekundarstufe I und II
Bodindecha (Sing Singhaseni) School

Juni 1994 - März 2000 Grundschule
Anubanphibunwes School
