The Transcriptomic Profiling Of Murine Embryonic Stem Cell-derived Mesodermal Cell Lineages And Functional Cardiomyocytes: An Insight Into Mesodermal Patterning

Inaugural-Dissertation

Zur

Erlangung des Doktorgrades

der Mathematisch-Naturwissenschaftlichen Fakultät

der Universität zu Köln

vorgelegt von

Michael Xavier Doss.J

Aus

Paramakudi, TN, Indien.

Köln, Februar 2007

Referees/Berichterstatter:

Prof. Agapios Sachinidis

Prof. Jürgen Hescheler

Prof. Diethard Tautz

Date of oral examination : 25th April 2007.

Tag der mündlichen Prüfung : 25th April 2007.

Declaration

The research work presented herewith was carried out by me under the supervision of Prof. Agapios Sachinidis, Prof. Jürgen Hescheler and Prof. Diethard Tautz at the Institute of Neurophysiology, Medical Faculty, University of Cologne, Germany from November 2003 to February 2007.

Erklärung

Diese Arbeit wurde von November 2003 bis February 2007 in institut für Neurophyiologie der Medizinischen Fakultät der Universität zu Köln unter der Leitung von Prof. Agapios Sachinidis, Prof. Jürgen Hescheler und Prof. Diethard Tautz angefertigt.

Ich versichere, dass ich die von mir vorgelegte Dissertation selbständig angefertigt, die benutzten Quellen und Hilfsmittel vollständig angegeben und die Stellen der Arbeit- einschließlich Tabellen und Abbildungen-, die anderen Werke im Wortlaut oder dem Sinn nach entnommen sind, in jedem Einzelfall als Entlehnung kenntlich gemacht habe; dass diese Dissertation noch keiner anderen Fakultät oder Universität zur Prüfung vorgelegen hat; dass sie- abgesehen von unten angegebenen beantragten Teilpublikationen- noch nicht veröffentlicht ist, sowie, dass ich eine Veröffentlichung vor Abschluss des Promotionsverfahrens nicht vornehmen werde. Die Bestimmungen dieser Promotionsordnung sind mir bekannt. Die von mir vorgelegte Dissertation ist von Prof. Dr. Agapios Sachinidis , Prof.Dr. Hescheler und Prof. Diethard Tautz betreut worden.

Köln den Michael Xavier Doss.J

Acknowledgements

First and the foremost, I would like to express my sincere gratitude to my supervisor Prof. Agapios Sachinidis and our institute director Prof. Jürgen Hescheler for their whole hearted support that they conferred through out my stay in the laboratory. I would like to thank very much Prof. Sachinidis for having given me the opportunity to carry out my research in his laboratory and his guidance and support all the way through. I am very grateful to Prof. Diethard Tautz, Institute of genetics, for his advise and valuable suggestions during my doctoral thesis work. I would like to thank specially Prof. Helmut W. Klein, Institute of Biochemistry, for chairing my thesis committee during my thesis defense.

I am very grateful to Prof. Hescheler whose initial ideas and constant efforts made "FunGenES" project sanctioned by the EU consortium. I gained a lot of thought provoking new ideas and excellent challenges from the experts in the fields of embryonic stem cell research thanks to the FunGenES project.

I would like to thank Prof. Francis Stewart, Technical University, Dresden for having given me a chance to attend the workshop on BAC Recombineering and providing the reagents. I would like to thank also Prof. Norbert Hübner, MDC, Berlin for the workshop on high throughput Affymetrix microarray data analysis and Affymetrix hybridization.

I would like to thank Mrs. Rita Altenburg for her kind assistance all the time in carrying out successfully all the large-scale experiments in very organized ways and for all those warm and friendly discussions, which I had with her during this time.

I would like to thank Dr. Norbert Huebner and his team Dr.Herbert Schulz, Dr. Oliver Hummel and also Dr. Jaak Vilo from Egeen, Tartu, Estonia for their Bioinformatics support in analyzing the large scale microarray data generated from all my lab experiments.

I would like to thank our collaborators Dr. Margarete Odenthal and Dr.Claudia Wickenhauser, Institute of pathology.

I would like to thank Miss. Ruth Rottscheidt, Insitute of Genetics for her kind help in Real time PCR analysis.

I am also thankful to the project-granting agency “European Community” (6th Framework Programme, Thematic Priority: Life sciences, genomics and biotechnology for health, Contract No: FunGenES LSHG-CT-2003-503494).

I am also thankful to ARTTIC community for their well-planned organizations for the FunGenES summer schools and workshops.

I would like to thank all the people of Institute of neurophysiology for their helpful scientific discussions, especially, Dr. Johannes Winkler, Kurt Pfannkuch, Dr. Tomo Saric and Dr. Dimitry Spitkovsky. I would like to thank Dr. Marcel Halbach and Miss. Huamin Liang for their help in electrophysiology. I also thank my lab collegues Shiva potta, Abdul Rahman Akasaha and Kleomenis Dardoussis.

I especially thank Prof.Schneider for having taken the responsibilities and his advice for our individual’s lab safety.

I would like to thank Mrs. Wood for her kind administrative support during my stay. I also thank Mr. Frank Stassen for his excellent computer support, Mr. Metzner and his team for the technical assistance.

I am also thankful to my former lab colleagues Miss. Conny Gissel who optimized the ES cell culture conditions and for her valuable scientific discussions, Dr.Vitam Kodelja who helped me to be familiar with the gene expression atlas.

During my stay here, I came in contact with several fascinating people with whom I shared great companionship especially Christoph Koehler, Kristine Obernier, Vijay Shankar and Velu.

I also thank 3Gs from Gastroenterology lab - Gita, Gudrun and Gissel for their kind help in fluorescence microscopy.

Last but certainly not the least, I would like to let my family know how much they mean to me. Without their support and constant encouragement, I would not come successful to this far.

Summary

The underlying basis of vertebrate mesodermal patterning by which the mesodermal cells become sequentially determined to more precisely defined cell fates during embryonic development remains largely unknown and is one of the classical problems in developmental biology. This demands an in-depth analysis of the endogenous signaling cascades and transcription factor networks. Till date, this fascinating puzzle is not yet solved since isolation of pure early stage mesodermal cells was not feasible due to practical difficulties and hence the functional genomics of the mesodermal cells has not yet been successful.

Recently, embryonic stem (ES) cells have been proven to be a promising tool to study the early embryonic development in a more physiological context *in vitro* because of their versatility over the other conventional systems. Furthermore, ES cells may revolutionize medicine by providing an unlimited renewable source of cells capable of replacing or repairing tissues that have been damaged in all degenerative diseases. Using ES cell model *in vitro*, for the first time pure populations of T Brachyury and BMP-2 expressing mesodermal lineages and mesodermal derived pure and functional cardiomyocytes have been isolated and their entire transcriptomes were profiled using microarrays. To isolate the pure lineage specific cells, stable transgenic ES clones transfected with a targeting vector construct in which the promoter of lineage specific marker (T, BMP-2 or αMHC) drives the expression of both puromycin resistance and enhanced green fluorescence bicistronically with the help of an IRES element were generated. The EBs made from these clones were treated at the onset of the particular transcript expression with puromycin to enrich the respective lineages.

Furthermore, analysis of the gene signatures specific to mesodermal cells and cardiomyocytes that defines their unique cellular and genetic identities contributing a major molecular insight into mesodermal patterning has been performed. In addition, a significant number of novel putative transcripts whose functions are unknown but expressed in specific lineages are enlisted. Few of these transcripts were functionally evaluated for their role in germ layer development and patterning. In addition, the purified populations of T Brachyury and BMP-2 mesodermal cells are capable of priming themselves to give rise to cardiomyocytes along with other mesodermal lineages. Interestingly, the BMP-2 positive cells contained predominantly neural crest stem cells (NCSCs) and their lineages namely smooth muscle cells, epithelial cells, melanocytes, and astrocytes along with cardiomyocytes. The transcriptome characterization of ES cell-derived αMHC cardiomyocytes clearly proves that these cells are exhibiting the properties more like the cardiomyocytes developed in *in vivo* conditions from the point of biological processes and hence are promising candidates for the future cardiac cell replacement therapy.

In overall, the part of the work presented here will better contribute substantially to the lineage specific transcriptomic atlas which will shed light in understanding the complex embryonic developmental process.

Zusammenfassung

Die grundlegenden Mechanismen des sogenannten “mesodermalen Patternings (Musters)”, durch welches sich mesodermale Zellen während der Embryonalentwicklung von Wirbeltieren nacheinander zu genau definierten Zelltypen entwickeln, sind weitgehend unerforscht. Für ein genaues Verständnis des “mesodermalen Musters” ist eine eingehende funktionelle Genomanalyse der endogenen Signalkaskaden und der beteiligten Transkriptionsfaktoren erforderlich. Bisher wurde das faszinierende Zusammenspiel dieser Faktoren nicht eingehend untersucht, da eine Isolierung von frühen mesodermalen Zellen aus experimentell-praktischen Gründen schwer durchführbar ist. Bisher existieren folglich diesbezüglich keine erfolgreichen Untersuchungen an mesodermalen Zellen.

Aufgrund ihrer *in-vitro*-Differenzierbarkeit können embryonale Stammzellen (ES-Zellen) als vielversprechendes Modell dienen, um frühe embryonale Entwicklungsprozesse in einem physiologischen Kontext zu studieren. Aufgrund dessen ist das ES-Zell-Modell herkömmlichen entwicklungsbiologischen *in vivo*-Modellen überlegen. Darüber hinaus können ES-Zellen die Medizin revolutionieren, indem sie als eine unbegrenzte Quelle erneuerbarer Zellen zur Verfügung stehen, die zur Reparatur oder als Ersatz für geschädigtes Gewebe eingesetzt werden können. Solche beschädigten Gewebe kommen in den meisten degenerativen Krankheiten vor.

Im Rahmen der vorliegenden Dissertation konnten aus ES-Zellen zum ersten Mal weltweit reine mesodermale T (Brachyury)- und BMP-2-positive Zellpopulationen sowie von mesodermalen Zellen abstammende, funktionelle Kardiomyozyten gewonnen und deren Transkriptom mittels DNA-Microarrays detailliert analysiert werden. Um diese reinen Zellpopulationen zu gewinnen, wurden ES-Zellen mit IRES-Vektoren stabil transfiziert, die gleichzeitig eine Puromycin-Resistenz-Kassette und eine Reporter-Kassette (grün fluoreszierendes Protein) unter der Kontrolle zellspezifischer Promotoren (T, BMP-2, αMHC) exprimieren. Diese transgenen Zelllinien wurden *in vitro* zu “Embryoid Bodies” (EBs) differenziert, aus denen nach Puromycinbehandlung die jeweiligen Zelltypen (T-, BMP-2-, und αMHC-positive Zellen) in reiner Form isoliert werden konnten

Die Analyse der Microarray-Expressionsdaten führte zur einer Identifikation zellspezifischer Genexpressionssignaturen für mesodermale Zellen sowie für Kardiomyozyten und somit zur Charakterisierung ihrer spezifischen zellulären und genetischen Identität. Diese Untersuchungen gewähren weiterhin einen Einblick in das“mesodermale Musters”. Darüber hinaus wurde eine große Anzahl von Transkripten ermittelt, deren Funktion bisher unbekannt ist. Einige dieser Transkripte wurden funktional bezüglich ihrer Rolle bei der Entwicklung von Keimblättern charakterisiert. Weiterhin konnte gezeigt werden, dass reine T Brachyury- und BMP-2-Zellen in der Lage sind, sich zu Kardiomyozyten und anderen gewebsspezifischen Zelltypen mesodermalen Ursprungs zu differenzieren. Interessanterweise wurden neben Kardiomyozyten zusätzlich Neuralleisten-Stammzellen, glatte Gefäßmuskelzellen, Epithelzellen, Melanozyten und Astrozyten nachgewiesen. Die Transkriptomanalyse der aus ES-Zellen abgeleiteten Kardiomyozyten zeigt, dass diese biologische Eigenschaften von *in vivo* Kardiomyozyten aufweisen und infolgedessen zukünftig für eine zelluläre Ersatztherapie von degenerativen Herzerkrankungen eingesetzt werden könnten.

Die vorliegende Arbeit wird zur Erstellung eines zellspezifischen Transkriptom-Atlas führen, der zu einem besseren Verständnis komplexer entwicklungsbiologischer Prozesse beitragen wird.

Abbreviations used

dpc	days postcoitum
EBs	Embryoid bodies.
μl	micro litre
ng	nanogram
d	day (s)
LB	Luria Bertani
IRES	Internal Ribosome Entry Site
LIF	Leukemia Inhibitory Factor
BMP-2	Bone morphogenetic protein-2
TGF	Transforming growth factor
αMHC	α-Myosin Heavy Chain (*Myh6*)

DNA	Deoxy ribonucleic acid
RNA	Ribonucleic acid
siRNA	small interfering RNA
qPCR	Qunatitative PCR
FACS	Flourescence Activated Cell Sorting

1. Introduction

Introduction

The vertebrate early stage embryo consists of three primary germ layers-the ectoderm, mesoderm and endoderm, from which all tissues of the adult are derived later. The mesodermal germ layer plays a fundamental role in organizing the vertebrate axes, and give rise to, among other structures, the skeletal, muscular, and circulatory systems. Mesoderm is an inducible fate, that is, the mesoderm is formed by a mechanism called induction[1]. Induction refers to a process in which extracellular signals bring about a change from one cell fate to another in a particular group of cells. The inducing factors and signaling cascades that regulate the differentiation and patterning of the mesodermal germ layer have been the focus for intensive study for the last decades.

1.1 Early embryonic development in mice

Much of the earlier investigation about the germ layer formation and patterning came from the *in vivo* experiments involving early embryos. Hence it is worthwhile to start with the actual developmental processes in early embryonic development in mice to better understand the process of mesodermal patterning.

1.1.1 Pre-implantation embryo

Prior to fertilization, the egg (oocyte) enlarges, divides by meiosis, and matures in its ovarian follicle until it reaches metaphase II, a stage of meiotic division. At this point, the follicle releases the haploid oocyte into the oviduct, one of two tube-like structures that lead from the ovaries to the uterus. The union of the oocyte and sperm and subsequent fertilization take place in the ampulla of the oviduct. The fertilized egg (zygote) divides and develops as it travels along the oviduct to the uterus (Figure 1). In mice, this process takes about 4-5 days. The egg has a protective membrane, the zona pellucida, which stops it from implanting in the oviduct wall.

By the time it reaches the uterus, the egg has undergone many cell divisions to form a blastocyst, which hatches from the zona pellucida to implant into the uterine wall. In all mammals studied, the pre-implantation stages are characterized by a relatively synchronous doubling of cell numbers until the 8-cell stage followed by asynchronous cell divisions after compaction[2]. During compaction, the blastomeres become polarized and develop tight junctions with the other blastomeres. At the 8-16 cell stage the embryo enters the uterine environment, developing into a blastocyst, in which the first events of cellular differentiation are observed (Figure 1).

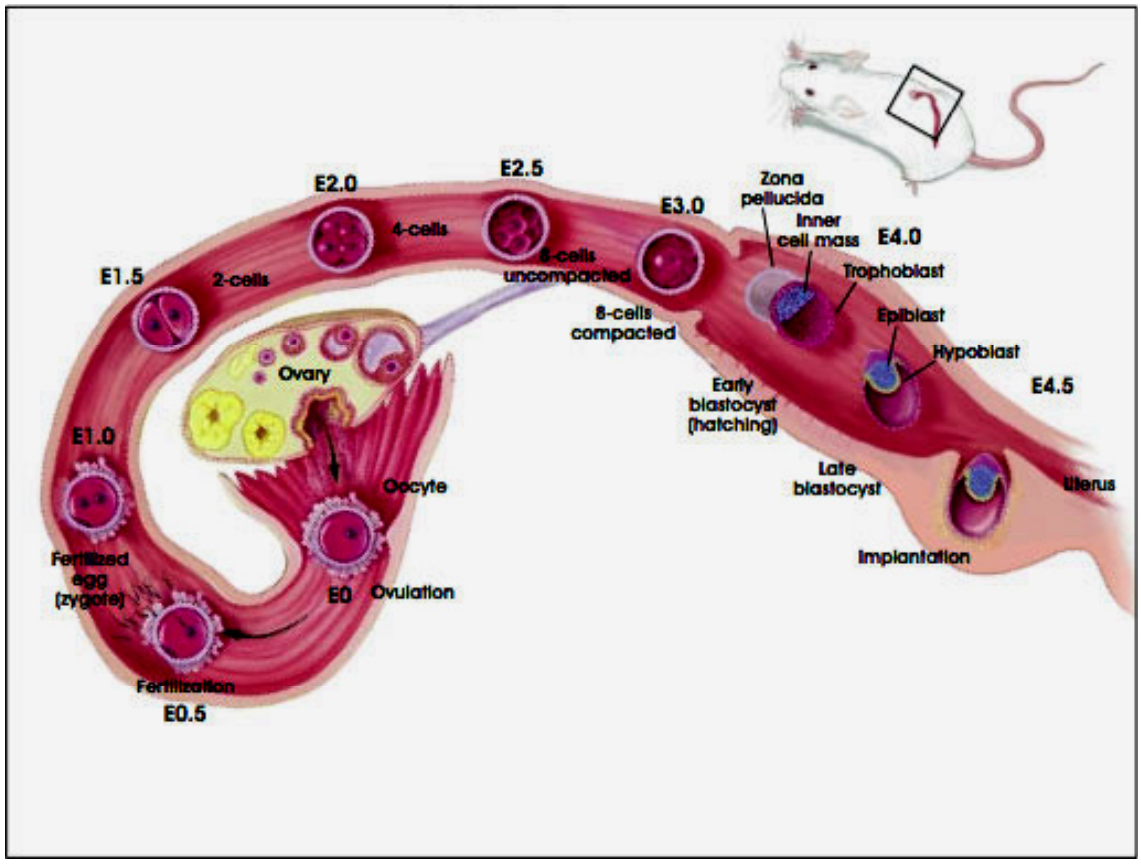

Figure 1. Development of the Preimplantation Blastocyst in Mice from Embryonic Day 0 (E0) Through Day 5 (E5.0). This picture was adopted from National Institutes of Health. Stem Cells: Scientific Progress and Future Research Directions. Stem Cell Information [online], http://stemcells.nih.gov/info/scireport (2001)).

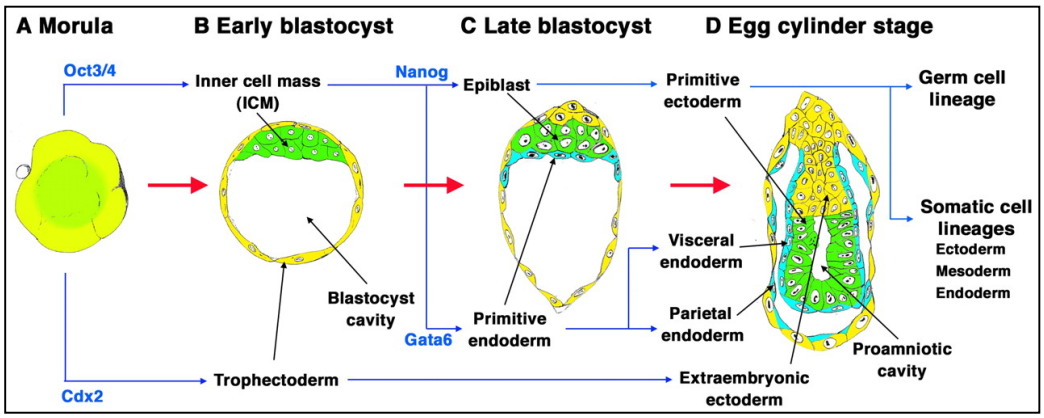

Figure 2. A schematic view of mouse pre-implantation development. (**A**) Pluripotent stem cells (green) are imaged in a morula as the inner cells, which (**B**) then form the inner cell mass (ICM) of the blastocyst. (**C**) After giving rise to the primitive endoderm on the surface of the ICM, pluripotent stem cells then form the epiblast and start to proliferate rapidly after implantation. (**D**) They then form the primitive ectoderm, a monolayer epithelium that has restricted pluripotency, which goes on to give rise to the germ cell lineage and to the somatic lineages of the embryo. Certain key transcription factors (blue) are required for the differentiation of the various embryonic lineages. Adopted from Niwa, H. Development 2007; 134:635-646.

1.1.2 Post Implantation embryo

Around the time of implantation, the mouse embryo is composed of three distinct cell types- the trophectoderm, the primitive endoderm, and the inner cell mass (ICM) (Figure 2, 3A and 3B)[3] . At approximately 4.5 to 5.0 dpc, implantation of the blastocyst into the uterus begins. Shortly after implantation, the ICM undergoes rapid proliferation and differentiates to form a pluripotent population known as primitive ectoderm. As the primitive ectoderm population expands, the innermost group of cells undergoes apoptosis, generating a cavity known as the proamniotic cavity. The remaining cells surrounding this cavity differentiate further to form a pseudostratified columnar epithelium, which results in the formation of a cup-like structure known as the epiblast[4]. Primitive ectoderm and epiblast cells differ from ICM cells in that they have upregulated Fgf5 expression, downregulated Rex expression and have lost their ability to generate chimeras following blastocyst injection[5-8]. Coinciding with development of the epiblast, primitive endoderm undergoes differentiation, giving rise to both visceral and parietal endoderm. Visceral endoderm forms a tissue that surrounds the epiblast, whereas parietal endoderm surrounds the extraembryonic tissues[9] (Figure 2 and Figure 3).

Gastrulation is the major milestone in early post implantation development. During gastrulation, pluripotent epiblast cells are allocated to the three primary germ layers of the embryo (ectoderm, mesoderm and definitive endoderm) and the extraembryonic mesoderm of the yolk sac and amnion. The primary germ layers are the progenitors of all tissue lineages. The specification of tissue lineage is accompanied by the restriction of the developmental potency and the activation of lineage specific gene expression. This process is strongly influenced by cellular interactions and signaling[10,11].

Although much remains unknown about how the embryonic axis is laid down in the mouse, it is now clear that reciprocal interactions between the extraembryonic and embryonic lineages establish and reinforce patterning of the embryo. At early post-implantation stages, the extraembryonic ectoderm appears to impart proximal–posterior identity to the adjacent proximal epiblast, whereas the distal visceral endoderm signals to the underlying epiblast to restrict posterior identity as it moves anteriorward. At gastrulation, the visceral endoderm is necessary for specifying anterior primitive streak derivatives, which, in turn, pattern the anterior epiblast. Polarity of these extraembryonic tissues can be traced back to the blastocyst stage, where asymmetry has been linked to the point of sperm entry at fertilization[2].

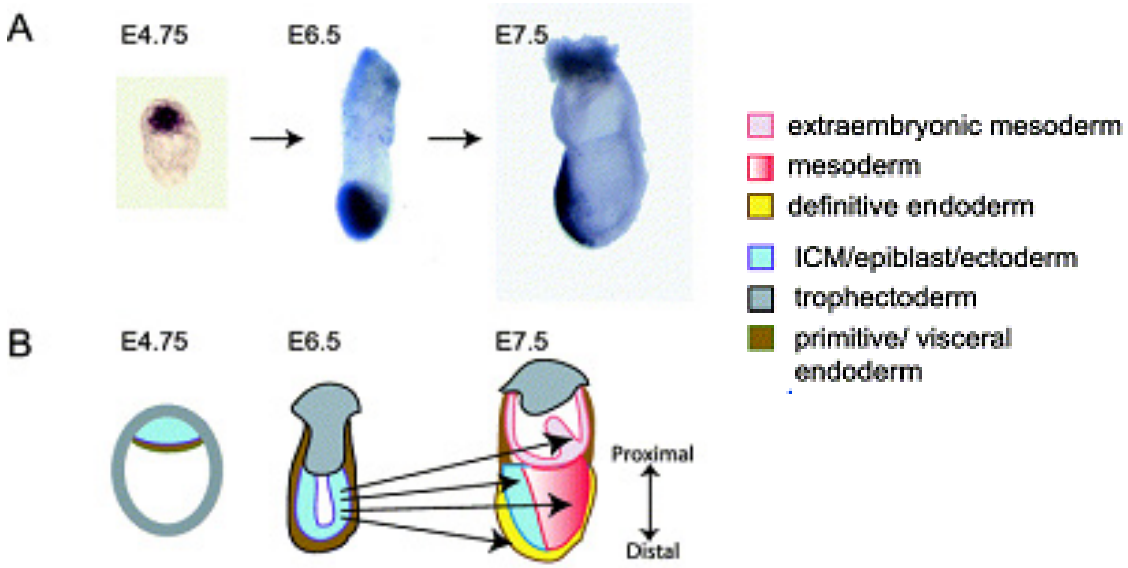

Figure 3. (A) Mouse embryo at peri-implantation (E4.75, *Pou5f1* expression in the ICM), early-streak (E6.5, *Otx2* expression in the epiblast), and early-bud (E7.5, *Cer1* expression in the anterior definitive endoderm) stages. (B) The differentiation of trophectoderm (grey), ICM (blue), and primitive endoderm (brown) of E4.75 embryo to the extraembryonic and embryonic tissues of E7.5 embryo (germ layer tissues are color-coded, see key). Taken from *D.A.F. Loebel et al. / Developmental Biology 264 (2003) 1–14.)*

1.2 Lineage specification

One of the distinguishing features of early mammalian development is the maintenance of a population of developmentally plastic, pluripotent stem cells, which give rise to all cells that constitute the mature organism. The earliest stage of lineage specification in the mouse embryo occurs at approximately 3.5 days post coitum (dpc) with formation of the blastocyst [12]. Around 10-20 cells, which appear to be developmentally equivalent, make up the inner cell mass (ICM), located at one end of the 3.5 dpc (days post coitum) blastocyst. Mammalian development entails the regulated proliferation of these cells and allocation of descendants to specific cell lineages following differentiation[13].

Around 4.0 days post coitum (dpc), ICM cells lining the blastocoelic cavity differentiate to extraembryonic primitive endoderm. Pluripotency is retained by internal ICM cells, referred to as the “epiblast”, now surrounded by extraembryonic endoderm and trophectoderm. At about the time embryo implants into the uterine wall these pluripotent cells begin to proliferate rapidly such that the 20-25 cells present at 4.5d.p.c expand to give rise to about 660 cells by 6.5dpc and 8060 cells by 7.5dpc[14]. Concurrent with pluripotent cell proliferation, primitive endoderm cells migrate along the pluripotent cell surface and differentiate into one of two cell types. Primitive endoderm cells that remain in contact with the pluripotent cells differentiate into visceral endoderm while those primitive endoderm cells

that migrate onto the blastocoelic surface of trophectoderm differentiate into parietal endoderm [9] (Figure 2).

Formation of the proamniotic cavity within the pluripotent cell population is first visible at 5.0dpc and is accompanied by reorganization of the cells into a pseudostratified columnar epithelial sheet. Concomitant with this process, the pluripotent cells become polarized, and undergo changes in gene expression and developmental potential suggesting that this morphologically distinct pluripotent cell population, termed primitive ectoderm, is derived from the ICM by differentiation. Primitive ectoderm provides the substrate for gastrulation, which is initiated at around 6.5 dpc. This process transforms the pluripotent monolayer into a multilayered embryo consisting of the 3 primary germ layers, mesoderm, endoderm and ectoderm. While coordinated regulation of pluripotent cell proliferation, differentiation and morphogenesis underpins development of the mammal, relatively little is known of the signaling mechanisms that regulate these processes at a cellular or molecular level. Accumulating evidence emerging from close analysis of gene expression and knock out phenotypes implicates visceral endoderm as a source of signals controlling primitive ectoderm formation, maintenance and differentiation[15].

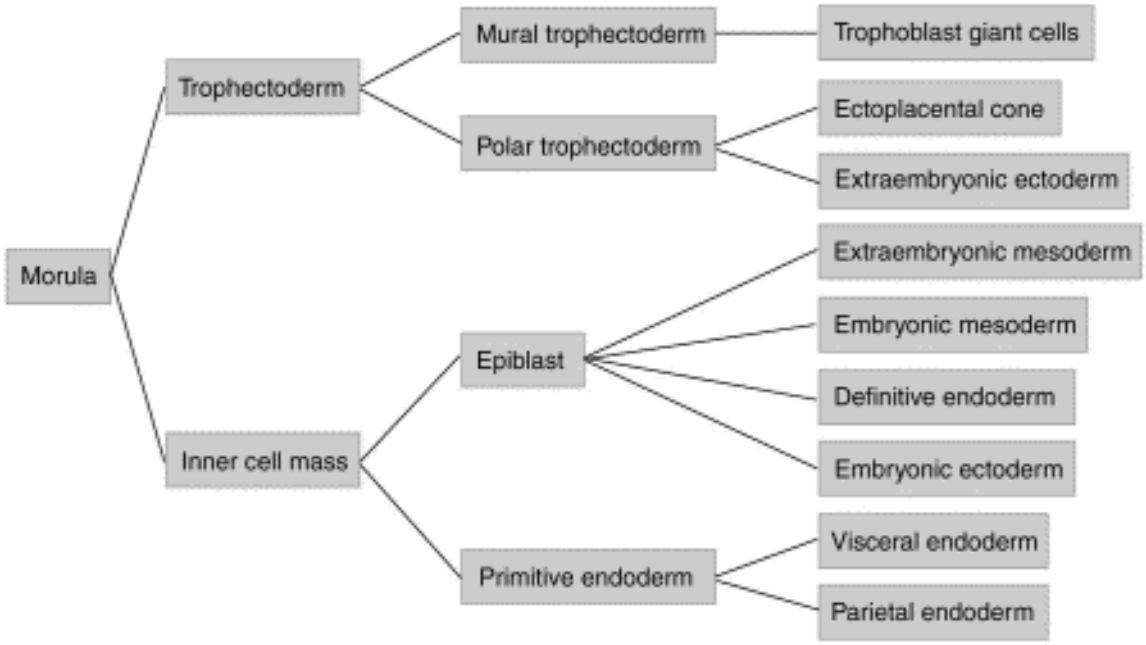

Figure 4. Cell lineage relationships in the early mouse embryo. Taken from Cindy C. Lu et al., Current Opinion in Genetics & Development Volume 11, Issue 4 , Pages 384-392.

The means by which cells are allocated to either embryonic or extra embryonic lineages in the blastocyst is not understood. However, the early establishment of cell fate may be regulated in part by the POU transcription factor *Pou5f1* (also known as *Oct4*). *Pou5f1* is expressed in all blastomeres at the four-cell stage but is downregulated in the trophectoderm by the blastocyst stage[16]. Its expression is maintained in the ICM, with highest protein concentrations accumulating in the primitive endoderm. *Pou5f1* is required for ICM formation, as *Pou5f1* mutant blastocysts consist only of trophectoderm[17]. Consistent with the mutant phenotype, recent studies have shown that embryonic stem (ES) cells lacking *Pou5f1* differentiate into trophectoderm, whereas cells expressing a single copy of *Pou5f1* maintain their pluripotent ES cell state. By contrast, a twofold increase in *Pou5f1* expression causes ES cells to adopt VE or mesodermal fates[18]. Thus, tight control of *Pou5f1* levels may be important for cell fate allocation in the blastocyst. It will be interesting to learn whether the initial polarity at fertilization or the timing of cell division in blastomeres is linked to expression levels of *Pou5f1*.Whereas *Pou5f1* mutant blastocysts lack an ICM, the novel gene *Taube nuss* (*Tbn*) seems to be required for survival or maintenance of the ICM[19]. *Tbn*-deficient embryos appear normal at the early blastocyst stage, but by late blastocyst stage consist only of trophoblast cells as a result of increased apoptosis in the ICM. Tetraploid aggregation experiments in which trophectoderm cells were wild type but ICM cells were mutant indicated that *Tbn* is required cell-autonomously for ICM survival. Another gene whose role in trophoblast development is the T-box gene *Eomesodermin* (*Eomes*), which is first expressed in the trophectoderm at the blastocyst stage[20]. Embryos lacking *Eomes* arrest at the blastocyst stage, and mutant trophectoderm dies in culture even in the presence of the trophectoderm proliferation factor Fgf4, suggesting that *Eomes* is required cell-autonomously for trophectoderm development.

Embryonic stem (ES) cells can be derived *in vitro* from the ICM of the peri-implantation embryo (Figure 5). Like the ICM and the early epiblast, ES cells are capable of differentiating into a wide range of fetal tissues in culture[21] or in chimeric embryos and can even form the entire fetus[22]. Trophectodermal stem (TS) cells, with the molecular properties of diploid trophoblast cells, may be isolated from the blastocyst or extra embryonic ectoderm of peri-implantation embryos. TS cells have a restricted differentiation potential: they can form giant cells in vitro [23,24] and have only been observed to contribute to trophectodermal cell lineages in vivo. Whereas ES cells can be induced to become TS cells[18], TS cells have not been shown to acquire the lineage potential of ES cells. As yet, there are no published reports of stem cells-derived from the third cell type, the primitive endoderm of the embryo, but this remains an exciting possibility (Figure 5).

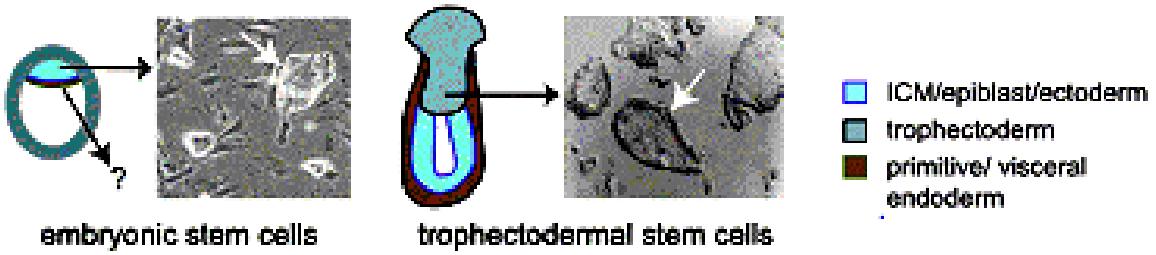

Figure 5. Colonies of embryonic and trophectodermal stem cells (white arrows) derived from the ICM and extra embryonic ectoderm, respectively. Taken from D.A.F. Loebel et al. / Developmental Biology 264 (2003) 1–14.

1.3 Mesoderm development

In mouse embryo, major decisions about lineage allocation and cell fate are made during gastrulation, between E6.25 –7.5[25]. Mesoderm is generated from the epiblast or embryonic ectoderm through the process of gastrulation that is initiated at approximately day 6.5 of gestation[10]. At the onset of gastrulation, the epiblast cells in the region that defines the posterior part of the embryo undergo an epithelial to mesenchymal transition and form a transient structure known as the primitive streak from which the mesoderm emerges. The newly formed mesoderm migrates away from the primitive streak, moves laterally and anteriorly and is patterned into various populations with distinct developmental fates. Brachyury is expressed in all nascent mesoderm and downregulated as these cells undergo patterning and specification into the derivative tissues including skeletal muscle, cardiac muscle and connective tissues in addition to blood and endothelium[26,27]. The first mesodermal cells to develop within the embryo contribute predominantly to the extra-embryonic tissues, giving rise to the hematopoietic and vascular cells of the yolk sac[28,29].

1.2.1 Major Molecular control of mesodermal differentiation

Wnt signaling

WNT3A signaling induces cells from the epiblast to adopt a paraxial mesodermal rather than a neuroectodermal fate after gastrulation[30] (for review[3]) . In *Wnt3a*$^{-/-}$ embryos, epiblast cells ingressing into the PS are diverted to a neuroectodermal fate instead of forming mesodermal cells. Consequently, ectopic structures resembling neural tubes are formed in place of the somites[30]. Regulation of genes acting downstream of WNT3A signaling requires the transcription factors *Lef1* and *Tcf1*. Mouse mutants lacking both *Lef1* and *Tcf1* develop ectopic neural tubes and are defective in paraxial mesoderm differentiation[31]. WNT3a signaling, via *Lef1/Tcf1,* maintains expression of the mesodermal transcription factor *T* in presumptive paraxial mesoderm[32]. Maintenance of *T* expression can be rescued by a constitutively active LEF1-β-catenin fusion protein[33]. The WNT signaling pathway interacts

with the FGF pathway to induce mesoderm differentiation (Figure 6, red area). *Fgfr1* is required for expression of *T* and *Tbx6*[34,35]. In chimeric embryos, ectopic neural tubes form entirely from *Fgfr1*$^{-/-}$ cells, which fail to fully traverse the PS and take on an ectodermal fate [30,36]. The phenotypes of *Fgf8* and *Fgfr1* mutant mice suggest a role in the migration of nascent mesoderm away from the streak, possibly by repression of E-cadherin[,35-38]. E-cadherin prevents the interaction of LEF/TCF proteins with the transcriptional co-activator β-catenin, disrupting WNT signaling. Sequestering E-cadherin rescues expression of a *T-lacZ* reporter, presumably due to the restoration of the WNT signaling pathway[35].

BMP signaling

BMP signaling is essential for the choice between ectodermal and mesodermal fates (for review [3]). BMP signaling is required to induce mesoderm formation *in vivo* (Figure 6, red area). Most *Bmp4*$^{-/-}$ embryos fail to gastrulate and form no mesoderm[39]. Loss of *Bmpr1* and *Bmpr2b* function also results in reduced epiblast proliferation and no formation of mesoderm [40,41]. The similarities in the phenotypes of *Bmp4, Bmpr1,* and *Bmpr2* mutants suggest that BMP4 signals predominantly through heterodimers of these receptors[40,41]. BMP signaling activates receptor regulated SMADs 1, 5,and 8, which interact with the common partner SMAD4 to regulate gene expression[42]. *Smad4* is required for epiblast proliferation, gastrulation, and mesoderm formation[43,44]. For correct patterning and differentiation of the embryo, the influence of BMP signaling must be modulated by antagonistic molecules. The BMP antagonists *Chordin* and *Noggin* are expressed in the mouse organizer and promote differentiation of ectodermal lineages (Figure 6, blue area). *Chordin* and *Noggin* have overlapping functions during embryogenesis and are required for anterior neural differentiation in the embryo[45].

Nodal signaling

Nodal, a member of the TGF-β superfamily is expressed throughout the epiblast in mice. Embryos mutant for *nodal* lack a proper primitive streak and show a severe reduction in mesoderm formation. Cofactors of Nodal belonging to the EGF-CFC family are essential for Nodal signaling and they have been found in *Xenopus*, fish and mouse. The mouse counterpart of these cofactors, *Cripto* is also expressed throughout the epiblast and null mutant mice fail to undergo the movements of the epiblast cell to the primitive streak and that of the anterior visceral endoderm to its proper location[46]. Further more, mutants for the Lefty/antivin proteins- a class of TGF-β molecules that antagonize Nodal in the mouse, zebrafish and *Xenopus* –display the opposite mutant phenotype to that of nodal. Mouse mutants exhibit an expanded primitive streak and excess mesoderm[47].

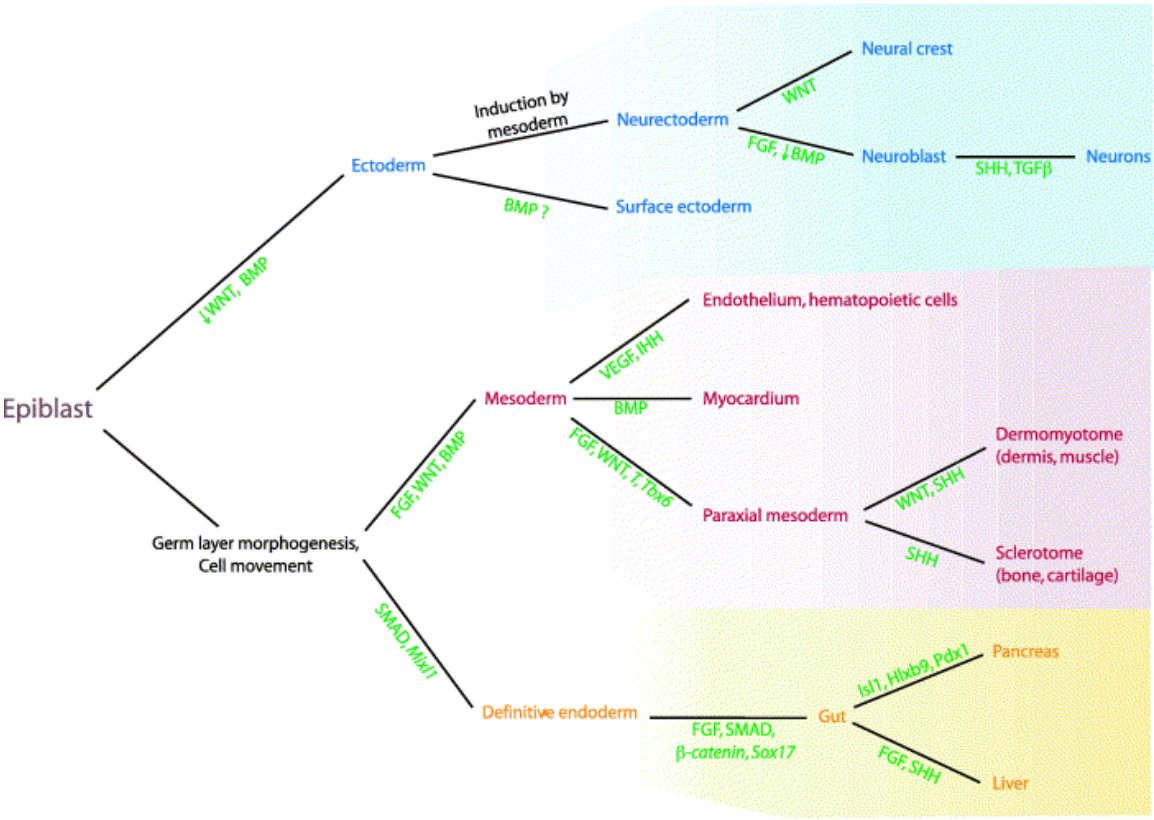

Figure 6. Specification and differentiation of germ layer derivatives in mouse embryos. Ectodermal (blue), mesodermal (red), and definitive endodermal (orange) lineages derived from the epiblast (brown) are shown, with the signaling pathways and transcription factors indicated in green. The question mark signifies the lack of direct evidence for involvement of BMP4 in surface ectoderm differentiation in mouse embryos. Taken from *D.A.F. Loebel et al. / Developmental Biology 264 (2003) 1–14.*

1.4 Cardiac development

The heart is the first organ to form during embryogenesis and its circulatory function is critical from early on for the viability of the mammalian embryo. The development of the vertebrate heart can be considered an additive process, in which additional layers of complexity have been added throughout the evolution of a simple structure (linear heart tube) in the form of modular elements (atria, ventricles, septa, and valves)[48,49]. Each modular element confers an added capacity to the vertebrate heart and can be identified as individual structures patterned in a precise manner. An understanding of the individual modular steps in cardiac morphogenesis is particularly relevant to congenital heart disease, which usually involves defects in specific structural components of the developing heart. Hence, the developmental mechanisms that orchestrate the formation and morphogenesis of this organ have received much attention among classical and molecular embryologists. The initiation of cardiac differentiation has been the topic of vigorous investigation. However, no single

transcription factor that is responsible for the differentiation of lateral plate mesoderm into cardiac cells has been identified[50].

Figure 7. Stages of Mouse cardiogenesis at E7.5, E8, and E8.5. Major heart forming field is shown in black and the anterior (secondary) heart-forming field (AHF) in gray. AS indicates atria, sinus venosa; CT, conotruncus; RV, right ventricle; LV, left ventricle; and A, atria. Adopted from Zaffran and Frasch, Circ Res 2002; 91:457-469.

In mouse, the heart arises from cells in the anterior lateral plate mesoderm of the early embryo, where they are arranged in bilateral fields on either side of the prechordal plate and rostral notochord [51]. These fields include the precursors of both myocardial and endocardial cells, although there is apparently no common pool of bipotential precursors for these two heart cell lineages[52,53]. The cells of the cardiogenic mesoderm are brought to these positions by gastrulation movements that occur in close association with ingressing cells of the rostral endoderm. In mammalians and birds, the bilateral fields of the cardiogenic mesoderm merge at their anterior margins to form the so-called "cardiac crescent"[54] (Figure 7). More recent studies have identified a second type of heart field that is located more medially in the splanchnic mesoderm, directly adjacent to the cardiac crescent. The cells from this bilateral field, termed anterior heart-forming field, are fated to generate anterior heart structures of the outflow tracts (see review[55] (Fig7and 8B). The specification of cardiomyocytes occurs just before or during the formation of the cardiac crescent, and differentiation markers become expressed shortly thereafter (review [51]). The earliest steps of assembly of the heart tube are initiated by the convergence and fusion of the bilateral heart primordia along the midline. The cells of the anterior heart-forming field, after having migrated anteriorly, are added to the anterior end of the linear tube during and after this period. The resulting beating tubular heart is composed of an external myocardial and an internal endocardial layer and also possesses a polarity along the anteroposterior axis, in which the prospective tissues of the aortic sac, outflow tract (conotruncus), right ventricle, left ventricle, and atria are present in an anterior to posterior order along the tube (Figure 7). In all

vertebrates, the tubular heart undergoes a process known as rightward looping. The morphogenetic steps required to achieve looping are guided by molecular asymmetries that are established in and around the heart by the embryonic left/right axial pathway. Furthermore, in higher vertebrates, septal division of the chambers and formation of the valves, which involves endothelial cells, are essential steps leading to the formation of an integrated 4-chambered heart with separate venous (or inflow) and arterial (or outflow) poles. During the growth process of the cardiac epithelium another distinct cell lineage, the migrating cardiac neural crest cells, populate the heart through the outflow channel and contribute to the formation of the great vessels and outflow septum[51].

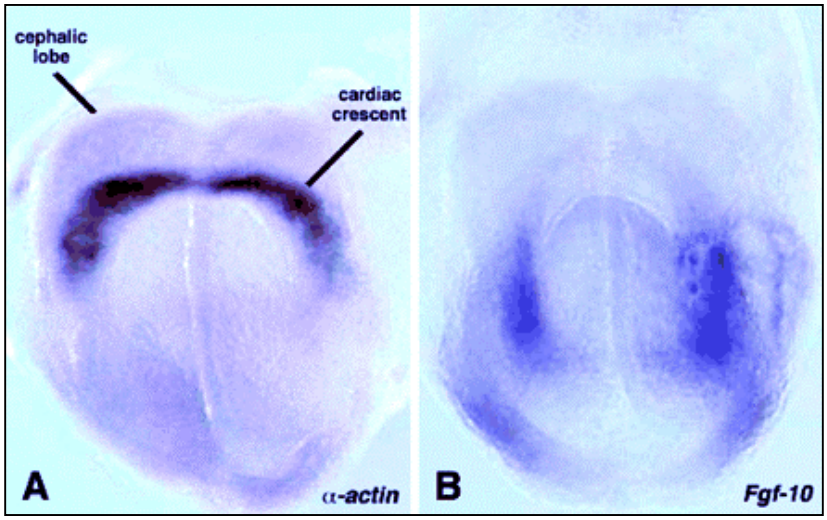

Figure 8. Early markers for the cardiac crescent (A) and anterior heart-forming field (B) in the mouse. Adopted from Zaffran and Frasch, Circ Res 2002; 91:457-469.

Transcription Factors involved during cardiomyogenesis

Heart formation requires the precise integration of cell type–specific gene expression and morphological development; both are intertwined in their regulation by transcription factors. Although many transcription factors have been described as regulators of cardiac-specific gene expression, the transcriptional regulation of cardiac morphogenesis is still not well explored. The most notable cardiac transcription factors and their roles in heart formation are summarized in Figure 9 and the transcriptional network in Figure 10.

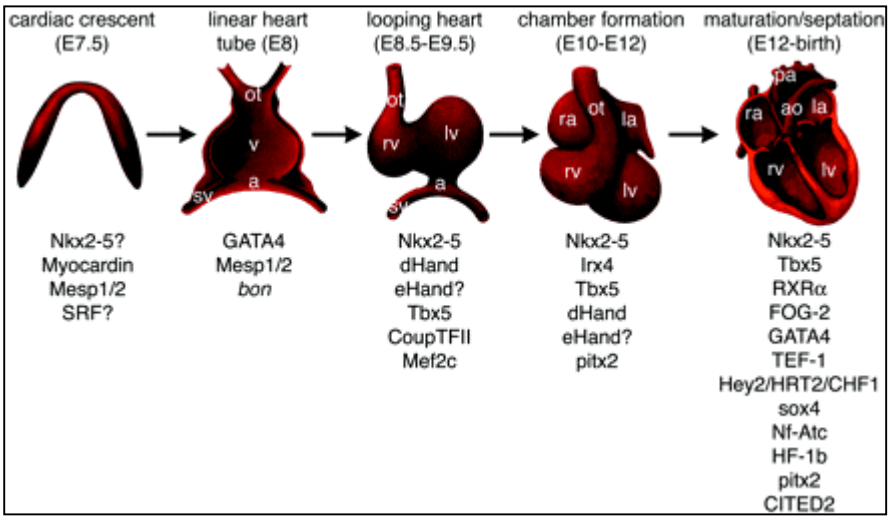

Figure 9. Summary of mouse heart development. Five major stages of heart development are shown: (1) cardiac crescent formation at embryonic day (E) 7.5; (2) formation of the linear heart tube at E8; (3) looping and the initiation of chamber morphogenesis at E8.5 to E9.5; (4) chamber formation; and (5) chamber maturation and septation and valve formation. The transcription factors involved or suspected of involvement in these processes are listed below each stage. ao indicates aorta; a, atrium; la, left atrium; lv, left ventricle; ra, right atrium; rv, right ventricle; ot, outflow tract; sv, sinus venosa; and pa, pulmonary artery. Adopted from Bruneau, B. G. Circ Res 2002;90:509-519.

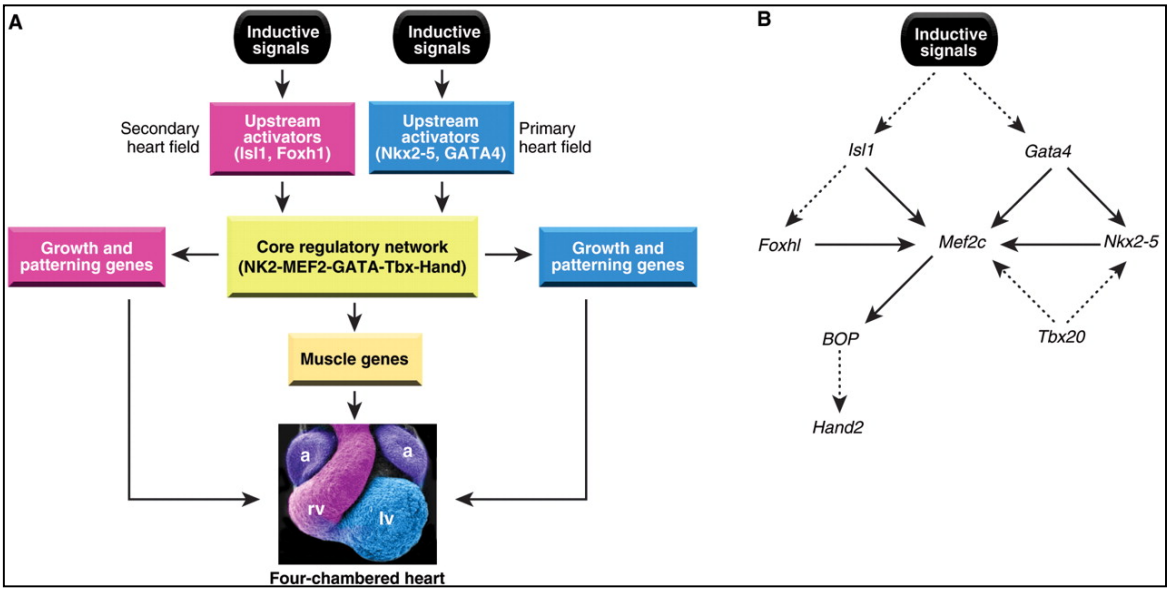

Figure 10. Schematic of transcriptional networks involved in mammalian heart development. (**A**) Inductive signals activate a set of upstream regulatory genes, encoding transcription factors, in the primary and secondary heart fields. The products of these genes activate the genes in the core cardiac network (NK2-MEF2-GATA-Tbx-Hand). Some components of the network, such as Nkx2-5, are also activated in the primary heart field in response to inductive signals. The core network genes cross- and autoregulate their expression and serve as the central regulatory network for the activation of muscle-specific genes and genes that control the growth and patterning of derivatives of the primary and secondary heart fields. The primary heart field gives rise to the left ventricle (lv) and portions of the atria (a), whereas the secondary heart field gives rise to the right ventricle (rv), portions of the atria, and the outflow

tract. A scanning electron micrograph of a mouse heart at embryonic day 14.5 is shown at the bottom. Derivatives of primary and secondary heart fields are shown in blue and pink, respectively. The atria, which are derived from the primary and secondary heart fields, are shown in purple. (**B**) Regulatory interactions among cardiac transcription factors in the secondary heart field. Solid lines indicate direct transcriptional connections, and dotted lines indicate connections not yet shown to be direct. [Adapted from Eric N. Olson, *Science* 29 Vol. 313. no. 5795, pp. 1922 - 1927]

Signaling Pathways During the Induction of Cardiogenic Mesoderm

BMP Signaling

The heart-inducing activity of BMP signaling has been confirmed by studies using inhibitors of BMP signaling, including the BMP inhibitor noggin, truncated versions of type I (tALK3) or type II (tBMPRII) BMP receptors, and inhibitory SMAD6[51]. These studies show that BMP signal transduction is indeed required within the cardiogenic mesoderm, and not only within the anterior endoderm, to promote cardiac differentiation. A second important conclusion from these data are that BMP signaling is required for the maintenance of *Nkx2-5, T-box* genes*, bHLH*-factor encoding *Hand* genes and *Gata* genes expression at stages during and after the fusion of the bilateral heart primordia, but apparently not for the initial activation of these genes in earlier stage embryos[56-58].

Fibroblast Growth Factor Signaling

Function of FGF signaling in cardiac induction has been obtained in the zebrafish system. Zebrafish FGF8 is expressed in the cardiogenic fields of the lateral plate, as well as in specific areas of the neural tube. *fgf8* (*acerebellar*) mutant embryos display strong heart defects with a particular loss of ventricular structures[59]. FGF signals not only act during early mesoderm development but are also required more directly for the induction of cardiogenic transcription factors during subsequent stages[51].

Notch Signaling

The direct target genes of Notch in heart development are not known. At least in certain contexts, the *Hrt* (*Hesr*/*Hey*) genes of the *Hairy/Enhancer of Split* family were proposed as candidates although there is presently no evidence that the differential expression of these genes along the anteroposterior axis of the heart tube is controlled via Notch signaling[60]. Nevertheless, the observations in *Xenopus*, the heart defects of hypomorphic *Notch2* mouse mutant embryos, and the heart abnormalities associated with *Jagged1* haploinsufficiencies in human Alagille syndrome patients indicate that Notch signaling is likely to be required during multiple processes in early vertebrate cardiogenesis[61].

1.5 Embryonic stem cells

-A versatile tool to study early embryonic development

The pluripotency and immortality of mouse embryonic stem ((ES) cells have made them attractive for basic studies of regenerative medicine, as well as for gaining molecular insight into cellular differentiation at early developmental stages, which are much more difficult to assess by *in vivo* approaches.

Due to their remarkable ability to recapitulate early embryonic development on their own, embryonic stem (ES) cells are revolutionizing the field of developmental biology as a potential tool to investigate the molecular mechanisms occurring during the process of differentiation from the early embryonic stage to the adult phenotype. ES cells harvested from the inner cell mass (ICM) of the early embryo can proliferate indefinitely in vitro culture without senescence in an undifferentiated state in the presence of leukemia inhibitory factor (LIF) or on the top of a layer of mitotically inactivated mouse embryonic fibroblasts (MEFs). In the absence of LIF, ES cells spontaneously differentiate into multicellular ES cell aggregates (ESCAs). These ESCAs, also called as embryoid bodies (EBs) represent a more physiological context in which the formation of germ layers-ectoderm, mesoderm and endoderm and their subsequent differentiation into several germ layer specific phenotypes can be studied more extensively than most other *in vitro* systems (Figure 11). The ES cell system offers several important advantages over the conventional studies in the early embryos such as the possibility to isolate large numbers of lineage specific cells in sufficient quantities at different developmental stages for molecular, biochemical, or functional studies using appropriate induction and selection strategies, access to the earliest stages of development to investigate the inducing and patterning properties of different soluble factors and relative easiness to genetically manipulate with loss or gain of function and to generate reporter cells lines to track the spatial and temporal expression of a particular gene of interest[12,62]. Thus ES cell differentiation system paves the platform for the discovery of new genes and serves as an elegant model for developmental biology as well as for its future potential in tissue replacement therapies.

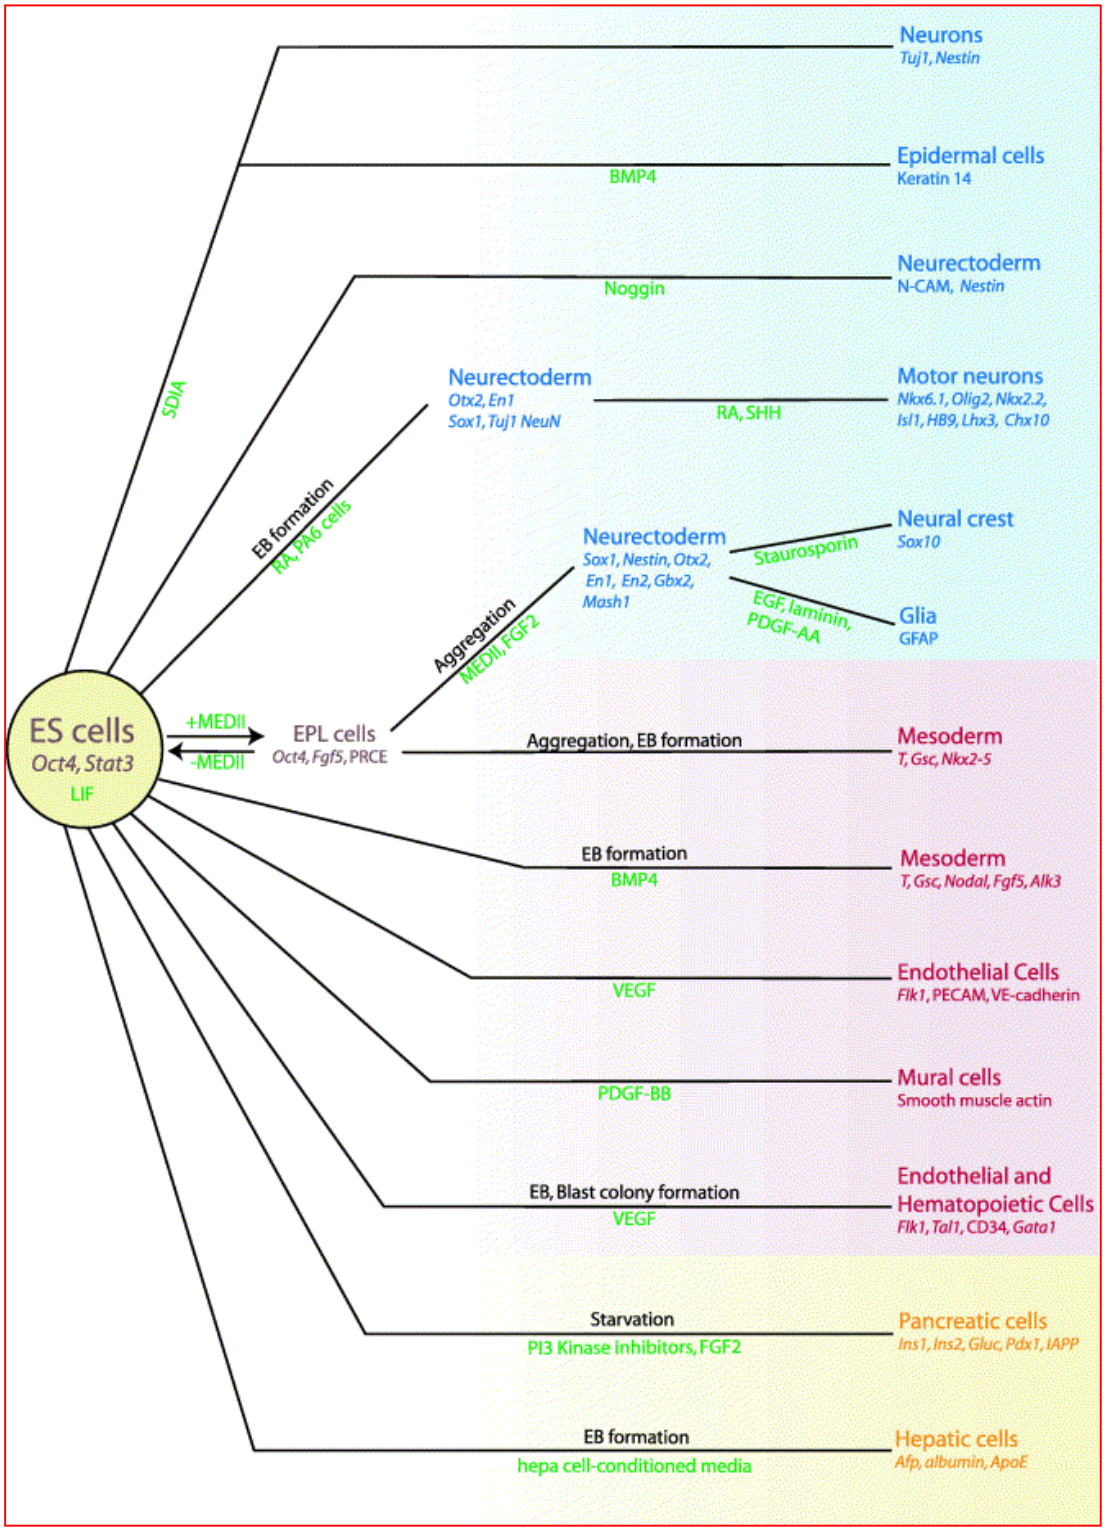

Figure 11. i*n vitro* differentiation of embryonic stem cells. Culture supplements are shown in green, culture conditions in black, and germ layer derivatives and tissue-specific markers in blue for ectodermal tissues; red for mesodermal tissues; orange for endoderm. EB, Embryoid body. Adopted from Developmental Biology Volume 264, Issue 1,1 December 2003, Pages 1-14.

2. Objective

During early embryonic development, the mesodermal cells become sequentially determined to more precisely defined cell fates and give rise to a diverse array of functionally important cell types, including the muscles, heart, vasculature, blood, kidney, gonads, dermis and cartilage. How the prospective mesodermal cells integrate the various signals they receive and how they resolve this information to regulate their morphogenetic behaviors and cell-fate decisions is largely unknown. This demands an in-depth analysis of the endogenous signaling cascades and transcription factor networks. Till date, isolation and transcriptome characterization of pure mesodermal cells have not been successful due to the practical difficulty in isolating the cells in pure form and in sufficient quantities from early stage embryos. This leaves a wider gap in our understanding about the mesodermal patterning. The present work is aimed to attempt to decipher the underlying mechanisms of mesodermal patterning during the differentiation of mesodermal cells into cardiomyocytes using ES cell model as an alternative approach and in particular to identify novel genes whose functions have not yet been annotated till date but are differentially expressed in mesodermal cells and cardiomyocytes.

The objective of this thesis work is to isolate ES cell-derived pure mesodermal cells and their lineages in order to characterize their unique transcriptomes by large scale microarray analysis and to functionally evaluate few of the novel transcripts, if any, for their role in development by “loss of function” and “gain of function” studies.

3. Materials and Methods

3.1 MATERIALS

ES cell line

CGR8 cell line (European Collection of Cell culture (ECACC), catalogue number: 95011018) was used. The germ-line competent cell line CGR8 was established from the inner cell mass of a 3.5-day male pre-implantation mouse embryo (Mus muculus, strain 129/ola). These cells retain the ability to participate in normal embryonic development. Differentiation of CGR8 cells is inhibited by the pleiotrophic cytokine Differentiation inhibiting Activity (DIA) which is identical to Leukemia Inhibitory Factor (LIF). Addition of DIA/LIF allows culture of CGR8 without the use of feeder layers. Karyotype: 40XY.

Self prepared media and solutions

SOC Media

SOC Media was prepared to be used in DNA transformation by dissolving 20g of bacto-tryptone, 5g of bacto-yeast extract, and 0.5g of NaCl in 950mL water, then adding 10mL of 250mM KCl. The solution was titrated to a pH of 7.0 by using NaOH, then diluted to 1L using water. The new solution was sterilized by autoclaving and cooled before adding 20mL of sterile 1M glucose and 5mL of sterile 2M $MgCl_2$.

TB buffer

Mixed 10 mM HEPES pH 6.7, 15 mM $CaCl_2$, 250 mM KCl and adjusted the pH to 6.7 with KOH. Then added 55 mM $MnCl_2$ and filter sterilized the mixture using a 0.22-µm filter.

SOB^{++} medium

Added 20 g bacto-tryptone, 5 g yeast extract, 0.5 g NaCl, 0.186 KCl, and the volume made up with distilled water to 1 litre. Sterilized by autoclaving and after cooled, added filer sterilized 10 mM $MgCl_2$, 10 mM $MgSO_4$ just before.

LB broth

Added 20g bacto-tryptone, 5g yeast extract and 5g NaCl in distilled water and the volume made up to 1 liter. The pH was adjusted to 7.2 at 37^0C. Autoclaved for 30 minutes.

LB Agar plates

Just before autoclaving the LB broth, added 15% agar-agar and then autoclaved. Once cooled to luke warm, added appropriate antibiotics and poured into plates. Once solidified, stored them in dark at 4^0C

Antibiotics

antibiotics	Stock solutions	Working concentration
Ampicillin	100 mg/ml in water	100 µg/ml
Chloramphenicol	30 mg/ml in ethanol.	15 µg/ml for BACs 50 µg/ml for high-copy plasmids.
Kanamycin	50 mg/ml in water	50 µg/ml
Tetracycline HCl	10 mg/ml in 75% ethanol.	2 µg/ml for pSC101-BAD-gbaA, 10 µg/ml for high copy plasmids

ES cell culture medium:

GMEM supplemented with 10% heat inactivated FBS, 100Units/ml LIF and 50 µM ß-2-mercaptoethanol (ß-ME). FCS has to be critically checked for optimal results for every batch.

Differentiation **medium**

IMDM supplemented with 20% FBS, 100 µM β-mercaptoethanol, and 1x concentrated MEM.

Freezing medium

10% DMSO in 90% FBS:

Wash medium

GMEM supplemented with 5% FBS.

Gelatine solution

5 g type II gelatine in 500 ml PBS was solubilized by heating in a microwave for 3 –5 minutes till clear solution was obtained. Autoclaved this 1% gelatine solution 30 min and stored at 4°C.

3.2 METHODS

3.2.1 ES cell culture

Gelatine coating of dishes

Added 5 ml of 0.2% gelatine solution (prepare diluting the 1% gelatine solution 1:5) per T25 flask and placed it in the sterile incubator for at least 3 hours before use for the best coating.

Defreezing cells

Prepared a 15ml falcon tube with 10ml wash media pre-warmed at 37°C.Thawed rapidly the vial at 37°C water bath. Once thawed, transferred all the contents into the falcon tubes with 10ml wash media. Centrifuged at 1000rpm for 6 minutes. Resuspended the pellet in 5ml medium with LIF Removed the gelatine solution contained in the culture flask. Transferred the cell suspension from the tube into the gelatine-coated dishes. Placed it in the incubator.

Passaging

Passaged the cells when they approach 70-80% confluency. Prepared new 0.2% gelatine coated flasks or dishes one day before. Aspirated the medium with a sterile Pasteur pipette. Washed cells with 5ml 37°C warm PBS Added 2ml Trypsin/EDTA solution. Incubated cells for 2-5min at 37°C until they have lost the contact to the flask. Rocked the flask in between. After 5-10 minutes, transferred the cells with trypsin into a 15 ml falcon tube with 10 ml wash medium. Centrifuged at Room Temperature for 6 min at 1000rpm Removed the supernatant with a sterile Pasteur pipette Resuspended the cells in 1ml propagation medium with LIF. Dispensed 0.2 to 0.3 ml of this cell suspension into 0.2% gelatine coated dishes with 5ml culture medium with LIF.

Counting cells

Prepared a cell counting chamber as described by the manufacturer. Added the appropriate volume of the cell suspension. Counted the cells under a microscope and calculate the total cell number in your cell suspension as described below. Prepared a 1 x 10^6 cells/ml cell suspension finally.

- Cell titer (cells/ml) = number of counted cells x chamber factor (Neubauer chamber = chamber factor 10^4)
- Number of total cells = cell titer x volume of cell suspension

Freezing cells:

When cells were around 70% confluency, frozen them. Aspirated the medium with a sterile Pasteur pipette. Washed cells with 5ml 37°C warmed PBS. Added 2ml Trypsin/EDTA solution. Incubated cells for 2-5min at 37°C until they had lost the contact to the flask. Rocked the flask in between. After 5-10 minutes, transferred the cells with trypsin into a 15 falcon tube with 10 ml wash medium. Taken an aliquot for cell counting. Centrifuged at room temperature for 6 min at 1000rpm. During centrifugation, counted the cells. Removed the supernatant with a sterile Pasteur pipette. Resuspended the cells quickly and carefully in ice cold freezing medium (the

titer should be 1 x10^6 cells / ml transfer into vials (put 1.5ml suspension into one vial). Placed on ice and stored it for two days at –80°C. Then transferred to Liquid N_2. Thawed one control vial to check everything ok with the freezing procedure 24 hrs after transfer to Liquid N_2.

Default differentiation protocol-Hanging drop protocol for Generation of embryoid bodies (EBs)

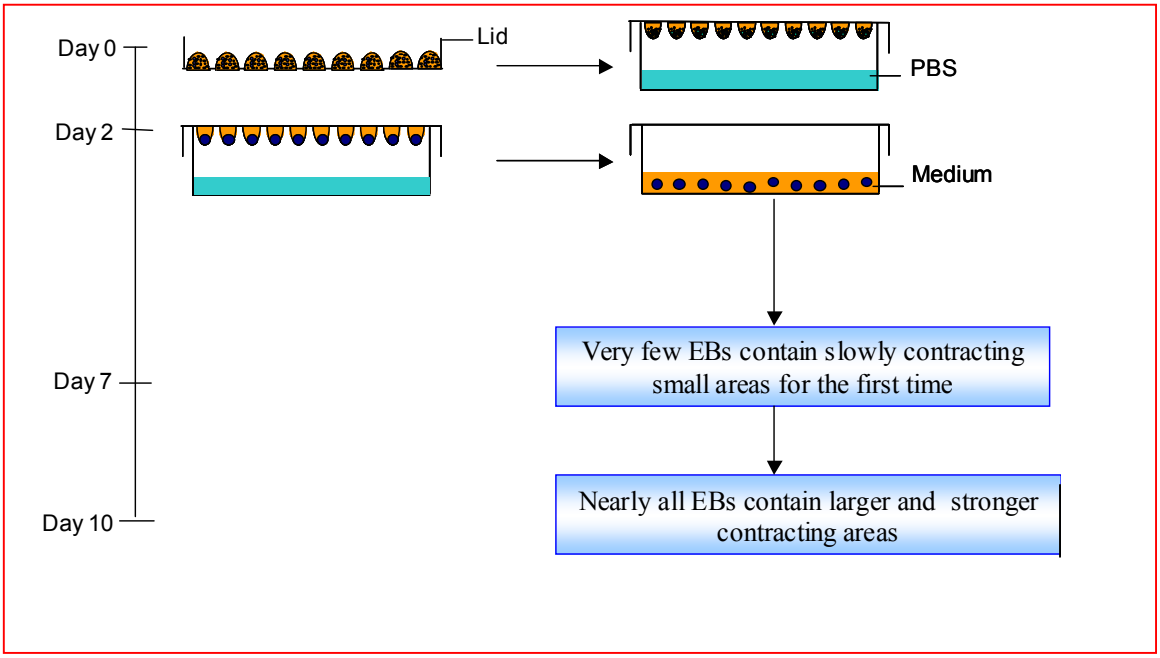

Figure 12. Schematic representation of the hanging drop protocol used for making EBs

Used a 70% confluent cell culture. Harvested the cells by trypsinisation and made viable cell counting with Trypan Blue dye exclusion method using Neubauer counting chamber. Cell suspension of 1X10^6 cells /ml was made initially. Then diluted 1:40 with EB differentiation medium to get the final titer of 2.5x10^4 cells per ml. Using a multi channel pipette, spotted 20µl of the cell suspension onto the inside of the upper lid of a10 cm bacteriological dishes with the lower lid containing 5ml PBS (Figure 12). Closed the dish carefully by inverting gently and incubated it for two days in the incubator for the cells spotted in droplets to form EBs. On day 2, the EBs were collected and transferred into a bacteriological dish containing 10ml of EB differentiation medium. Made medium change whenever the medium turns little yellow and made sure that the EBS don't starve of the medium. On 7^{th} –8^{th} days, first contractile areas will observed and almost all EBs will be contracting.

3.2.2 Basic Molecular Biological Methods.

DNA agarose gel electrophoresis

Agarose gel electrophoresis was performed to analyse the length of DNA fragments after restriction enzyme digests and polymerase chain reactions (PCR), as well as for the purification of PCR products and DNA fragments. DNA fragments of different molecular weight show different electrophoretic mobility in an agarose gel matrix. Optimal separation results were obtained using 0.5-2% gels in TAE buffer at 10 V/cm. Horizontal gel electrophoresis apparatus of different sizes were used. Before loading the gel, the DNA sample was mixed with 1/6 volume of the 6x DNA-loading buffer. For visualization of the

DNA fragments under UV-light, agarose gels were stained with 0.1µg/ml ethidium bromide. In order to define the size of the DNA fragments, DNA molecular standard markers were also loaded onto the gel.

BAC DNA isolation

Picked colonies and inoculated in 2 ml of LB culture containing the appropriate antibiotics. Incubated at 37°C over night with shaking at 1100 rpm. Next day, spun down the 2 ml over night cultures for 1 min at 11,000 rpm. Discarded the supernatant and resuspended the cell pellet in 200 µl buffer P1 with RNase (from QIAGEN DNA Maxi-preparation Kit). Added 200 µl of buffer P2 (Qiagen) and mixed by inverting the tube several times. Added 200 µl of buffer P3 (Qiagen) and mixed by inverting the tube several times. Spun down the white lysate at highest speed for 4 min. Transferred the clear supernatant into a new 1.5ml-Eppendorf tube and added 0.50 ml of 2-propanol. Mixed by inverting the tube and spin down the DNA at highest speed for 5 min. Discarded the supernatant and add 1 ml of 70% ethanol to rinse the pellet.10. Dried the pellet under the speed vacuum for 2 min or leave the tube open on the bench for 5 to 10 min until the DNA pellet is completely dried. The BAC DNA was resuspended in 10mM Tris-HCl, pH 8.0. Stored at 4^0C.

Plasmid and DNA isolation

QIAprep Spin Miniprep Kit and EndoFree Plasmid Maxi Kit were used for the isolation of plasmid DNA and followed exactly the manufacturers protocol.

Preparation of chemically competent DH5α E.coli

Inoculated 3 ml LB medium with the DH5α *E. coli* strain and incubated the culture overnight at 37°Cin an orbital shaker. The next day, added the overnight culture to 500 ml SOB^{++} medium and incubated the culture at 25-30°C until the absorbance at 600 nm reached approx. 0.5 (between 0.4 and 0.6). Chilled the culture for at least 10 min on ice. In the following steps, the cell suspension was kept on ice as much as possible. Centrifuged the cell suspension for 10 min at 4,500 rpm (Sorvall RCB4 rotor) or 6,000 rpm (Sorvall GSA rotor) at 4°C. Gently resuspended the pellet in 100 ml ice-cold TB buffer. Incubated the cell suspension on ice for 10 min. Centrifuged for 10 min at rpm (Sorvall SS-34 rotor) at 4°C. Gently resuspended the pellet in 18.6 ml ice-cold TB buffer and add 1.4 ml DMSO. Incubated the cell suspension on wet ice for at least 10 min. Aliquoted the cell suspension 200 µl per 1.5ml eppendorf tube. Shock-frozen the cell suspension in liquid nitrogen and stored the tubes at -80°. The transformation efficiency of the competent cells was determined using 5 ng of pure plasmid DNA and 200 µl competent cell suspension (see transformation protocol). This gave approx 1 x 10^8 transformants per µg plasmid DNA with DH5 α.

Transformation of chemically competent cells by heat shock

Transformation of DH5α *E.coli* with plasmid DNA was performed by incubating 200 µl of the competent cell suspension on ice after taken from the -80° storage followed by heat shock at 42^0C for 45 seconds and the subsequent incubation on in ice for 5 minutes. Then, 750ul SOC media was added and incubated at 37 in orbital shaker for 45 –60 minutes. Then the cells were plated onto the top of the agar plates containing the appropriate antibiotics.

3.2.3 Recombineering

Oligo design

Chosen 50 nucleotides immediately of the left of region to be subcloned from the BAC Ordered an oligonucleotide with this sequence at the 5' end and 3' end of this oligo included PCR primer sequence for amplification of the ColE1+amp template, given in *italics*

5'-(N)50 *TCACAGCTTGTCTGTAAGCGGATG* -3'. Chosen 50 nucleotides immediately right of the site to be subloned and transferred them into the ***reverse complement orientation***. Ordered an oligonucleotide with this sequence at the 5' end and the 3' end of this oligo included the 3' PCR primer sequence for the ColE1+amp template, given in *italics* 5'-(N)50 *GCTCTCCTGAGTAGGACAAATC* -3'. Included restriction sites between the 5' homology regions and the 3' PCR primer sequences.

PCR

The oligonucleotides were suspended in dH_2O at a final concentration of 25 pmol/µl. PCR reaction was set up in volume of 50 µl with 38.5 µl dH_2O, 5.0 µl 10 x PCR reaction buffer, 2.0 µl 5 mM dNTP, 1.0 µl upper oligonucleotide, 1.0 µl lower oligonucleotide, 2.0 µl ColE1+amp template and 0.5 µl Taq polymerase (5 U/µl). The following thermal conditions were used. 95^0C for 60 sec, 57^0C for 30 sec and 72° C 2min. 30 cycles. Checked 3 µl PCR products on a gel to ensure the PCR was successful. The size of the PCR product is around 2.7kb . Precipitated using 5 µl 3 M sodium acetate, pH 7.0, and 150 µl 100% ethanol. Mixed well and precipitate for 5 min at -80°C or 30 min at -20°C. Spun down the DNA at maximal speed for 5 min. Carefully washed the pellet once with 500µl 70% ethanol. Dried the pellet at 37°C using a heating block for 5 -10 min or vacuum dry for 2 min. Resuspended in 5 µl 10mM Tris-HCl, pH 8.0 (0.2 -0.5 µg/µl).

Electroporation of the Red/ET Plasmid pSC101- tetR-gbaA into the E.coli strain carrying the BAC with the gene of interest

Set up an overnight culture. Picked at least ten colonies carrying the BAC and inoculated them together in an Eppendorf tube containing 1.0 ml LB medium with appropriate antibiotics to select for your endogenous BAC. Punctured a hole in the lid for air. Incubated at 37ºC over night with shaking. Next day, set up an Eppendorf tube containing fresh 1.4 ml LB medium conditioned with the same antibiotics and inoculated with 30 µl of fresh overnight culture. Cultured for 2-3 hours at 37ºC, shaking at 1000 rpm. Centrifuged for 30 seconds at 11,000 rpm in a cooled Eppendorf benchtop centrifuge (at 2°C). Discarded the supernatant by quickly tipping out the supernatant twice, and place the tube on ice. Resuspended the pellet with 1 ml chilled dH2O, pipetting up and down three times to mix the suspension. Repeated the centrifugation and resuspended the cells again. Centrifuged and tip out the supernatant once more; 20 to 30 µl will be left in the tube with the pellet. Kept the tube on ice. Added 50ng the Red/ET recombination protein expression plasmid pSC101-tetR-gbaA and mixed gently. Kept the tube on ice. Fitting a larger pipette to the same tip, transferred up to 30 µl of cell suspension from the tube to the chilled electroporation cuvette. Electroporated at 1350 V, 10µF, 600 Ohms. with an Eppendorf® Electroporator 2510 using a 1 mm electroporation cuvette. Resuspended the electroporated cells in 1 ml LB medium without antibiotics and returned them to the Eppendorf tube. Incubated at 30ºC for 70 min, shaking at 1000 rpm. Using a small loop, plated 100 µl cells on LB agar plates containing tetracycline (25 µg/ml) plus the appropriate antibiotics for the BAC. Incubated the plates at 30°C overnight (or for at least 15 hours).

Subcloning

Once the cultures were incubated at 30^0C , the cells were induced with arabinose incubated for 1 hour with shaking at 1100rpm. Then the PCR product with the homology arms were electroporated as mentioned above. Then the cells were plated on LB agar plates prepared with appropriate antibiotics. The next day, the colonies were analyzed with restriction digestion for the subcloned construct.

3.2.4 Generation of ES cell targeting construct and clone generation

ES cell targeting construct

pIRES2 EGFP was purchased from Clontech, Germany. Human cytomegalovirus (CMV) immediate early promoter and enhancer were removed by a double digestion with *Nhe I* and *Ase I* and then subsequently blunt end ligated to get pIRES2 EGFP ϕ CMV. Puromycin cDNA flanked on its both ends by BamH1 restriction sites which was PCR amplified from pIRESPuro3 by *Pfu* DNA polymerase (Promega, Germany was inserted at the *Sma I* site of pIRES2 EGFP φ CMV construct to get pPuro IRES2 EGFP

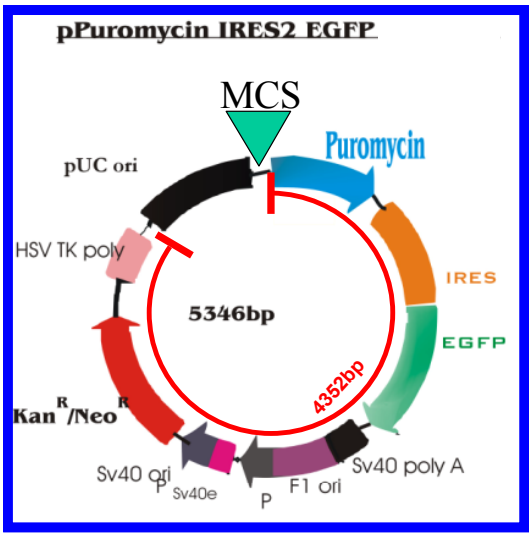

Figure 13. Plasmid map of pPuro IRES2 EGFP. This vector was constructed to derive the expression of puromycin N acetyl transferase to confer puromycin resistance and EGFP bicistronically with use of an IRES element. The multiple cloning sites just upstream of puromycin resistance cassette can be used to clone the promoter of interest to generate a reporter construct for a gene of interest. The plasmid encodes for neomycin resistance for selecting the transformants after electroporation and is the under the control of a ubiquitous promoter (SV40 promoter).

Clone Generation

30-40 μg plasmid was linearised in 100 μl reaction with appropriate enzyme(s). The enzyme is then heat inactivated at 80^0 C in a PCR machine or phenol chloroform extracted if the enzyme is resistant to heat inactivation at 80^0 C. Then the DNA was added to 10^7 cells in the Gene pulser electroporation cuvette and incubated on ice for 20 minutes before the electroporation. Then, the cells were electroporated with 500μFD and 0.24 Volts to get a time constant of around 9.8 for optimal results. The cuvette with the cells was place on ice and incubated for the next 10 minutes. The electroprated cells were divided equally to seed 3 gelatine-coated petriplate (100m diameter) with 10 ml media. At the end of 48 hours, antibiotic selection was applied to obtain stable transfectants either with neomycin at 400ug/ml or puromycin at 3ug/ml. When the negative background was cleared, around 9-11 days post transfection, the colonies were picked with aid of a microscope and propagated in the normal way

Generation of βactin clone expressing Puromycin resistance and EGFP constitutively

1.7kb βactin promoter excised from pCAGGS (kindly provided by Dr. Miyazaki, Tohoku University) with EcoRI and SalI was blunt end ligated to EcoRI digested, klenowed and 5' dephosphorylated pPuro IRES2 EGFP to get pβactin^p Puro IRES2 EGFP. This was then linearised with *SacI* and electroporated in CGR8 ES cell line and the neomycin resistant clones were picked, propagated and analyzed for the functional integrity of the targeting vector.

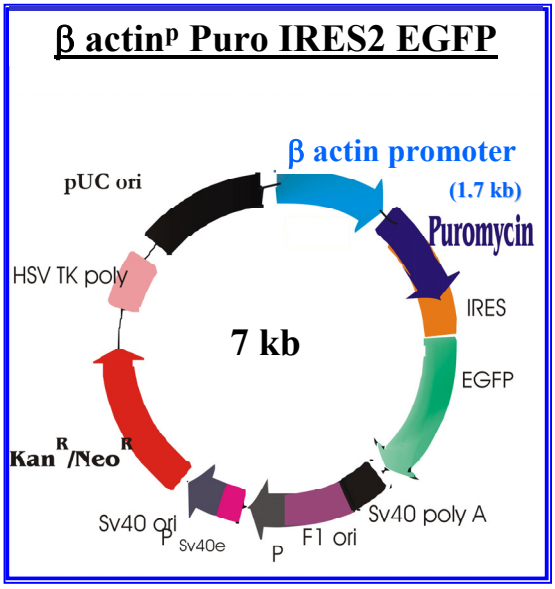

Figure 14. Plasmid map of pβactin^{p}Puro IRES2 EGFP

3.2.5 Derivation of T-brachyury lineages

T-brachyury Promoter Cloning by Recombineering

5kb promoter region upstream of the translation initiation site of the T-brachyury gene was subcloned from a BAC into the ES cell targeting construct pPuroIRES2 EGFP by a recombineering approach as follows (Figure 15). Sequences of 50 bases flanking on either side of the promoter region to be subcloned were verified by sequencing. Each 50b sequence was added to the 5' end of the forward/reverse primers with appropriate restriction enzyme recognition sites in between (Figure 16). These primers were then used to amplify the linear minimal vector containing ColE1 origin and Ampicillin resistance cassette. The linear amplified product was electroporated into the *E.Coli* harboring the BAC and induced to express Red ET proteins. Due to the homologous recombination events mediated by the Red E/T proteins and the 50bp homology regions, the minimal vector containing the promoter was positively selected with ampicillin. Then the minimal vector was digested with the appropriate restriction enzymes to release the T-brachyury promoter, which is then ligated in pPuroIRES2 EGFP to get pT-bra^{p} PuroIRES2 EGFP. This was then linearised and electroporated in CGR8 ES cell line and the neomycin resistant clones were picked, propagated and analyzed for the functional integrity of the targeting vector.

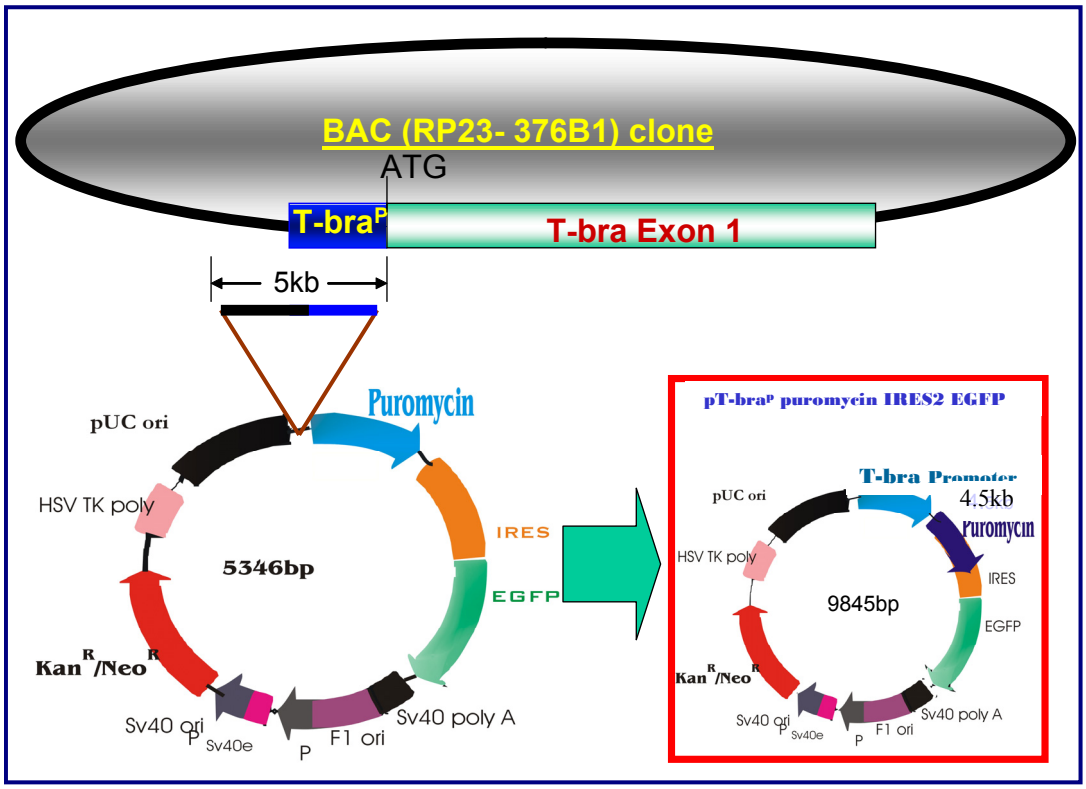

Figure 15. The overall view of the BAC subcloning by recombineering approach to clone T Brachyury promoter in the reporter vector approach.

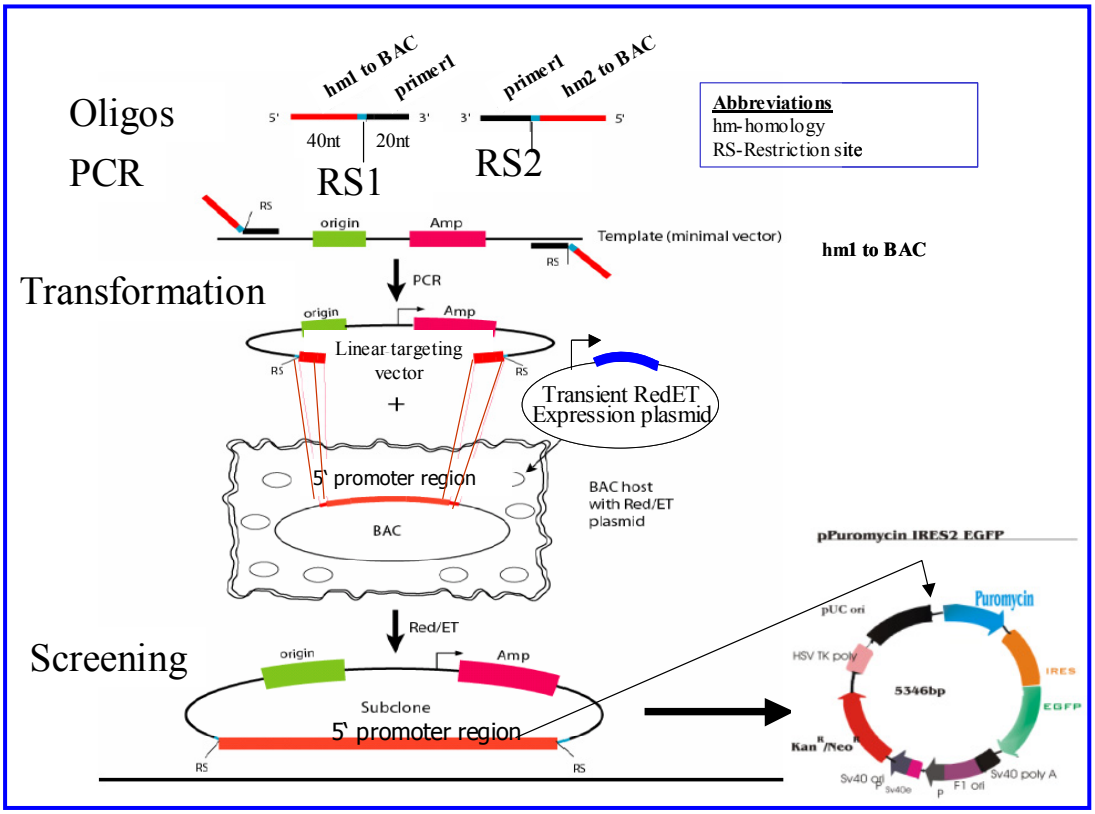

Figure 16. Schematic representation of recombineering process involved in sub cloning the T brachyury promoter from BAC.

Generation of T brachyruy reporter construct and reporter ES cell clones.

The 4.5 kb T Brachyury contained in the minimal vector was excised with *Bgl II* and ligated to *Bgl II* digested and terminal 5' phosphate removed (by calf intestinal phosphatase) pPuro IRES2 EGFP to generate pT Bra^{+} Puro IRES2 EGFP. The plasmids cloned in the right orientation were screened by restriction digestion with other enzymes and one among was checked by sequencing before electroporation. . This construct was electroporated in CGR8 with 500µF and 240V in a Bio-Rad Gene Pulser^{TM}. The transfected clones were selected by 400 µg/ml neomycin and after selection, the clones were maintained with 200µg/ml neomycin.

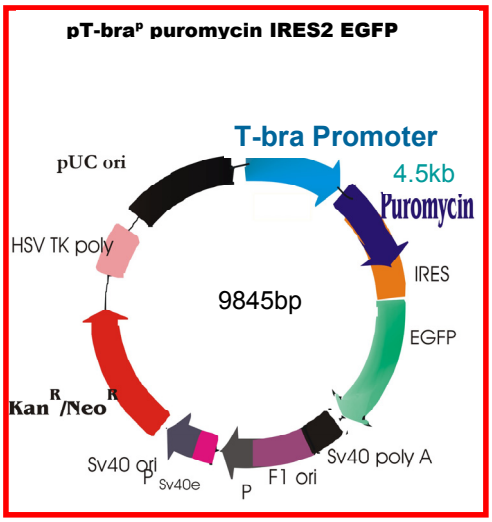

Figure 17. Plasmid map of T Brachyury reporter ES cell targeting construct

3.2.6 Derivation of BMP-2^{+} lineages

Generation of BMP-2 reporter cell line

A 2.9 kb BMP-2 promoter fragment with both proximal and distal transcription start sites, excised with Hind III and sac I digestion from pBMP-2-GL3 (kindly provided by Nandini Ghosh-Choudhury,USA) were blunt end ligated to EcoRI digested and klenowed pPuro IRES2 EGFP to generate pBMP-2^{p} Puro IRES2 EGFP. This BMP-2 reporter construct drives the expression of both puromycin resistance and EGFP under the control of BMP-2 promoter by the use of IRES sequence. This construct was electroporated in CGR8 with 500µF and 240V in a Bio-Rad Gene Pulser^{TM}. The transfected clones were selected by 400 µg/ml neomycin and after selection, the clones were maintained with 200µg/ml neomycin. During the EB generation, the neomycin selection was discontinued.

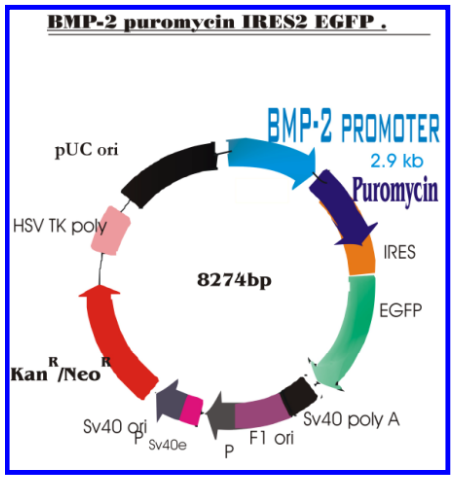

Figure 18. Plasmid map of BMP-2 reporter ES cell targeting construct

Isolation of BMP-2$^+$ cells

To induce differentiation, ES cell suspension of 1.6x10^4 cells/ml was made in IMDM supplemented with 20% FCS, 1% none-essential amino acids (vol/vol), 2 mM L-glutamine and 100 µM β-ME. Each bacteriological dish containing 25 ml of this ES cell suspension was placed in a 37^o C incubator with 5% CO_2 for 2 days. Then the 2-days old EBs were transferred into a 0.2% gelatine coated 10 cm tissue culture dish. On day 4, the EBs were treated with 3µg/ml puromycin for subsequent 3 days with every day medium change with fresh puromycin. On day 7, the puromycin resistant BMP-2$^+$ cells were used for the experiments.

3.2.7 Derivation of αMHC lineages

Generation of αMHC reporter construct and αMHC ES clones.

The 5.5 kb αMHC promoter construct was a kind gift from Dr. J. Robbins (Cincinnati, OH). The promoter was klenowed on one end and the other end digested with *Sac*II was inserted with one end *Eco*RI digested and klenowed and other end digested with *Sac*I fragment of pPuro IRES2 EGFP to generate p αMHC^p Puro IRES2 EGFP. This αMHC^p reporter construct drives the expression of both puromycin resistance and EGFP under the control of αMHC promoter by the use of IRES sequence. This construct was electroporated in CGR8 with 500µF and 240V in a Bio-Rad Gene Pulser^{TM}. The transfected clones were selected by 400 µg/ml neomycin and after selection, the clones were maintained with 200 µg/ml neomycin. During EB generation, the neomycin selection was discontinued.

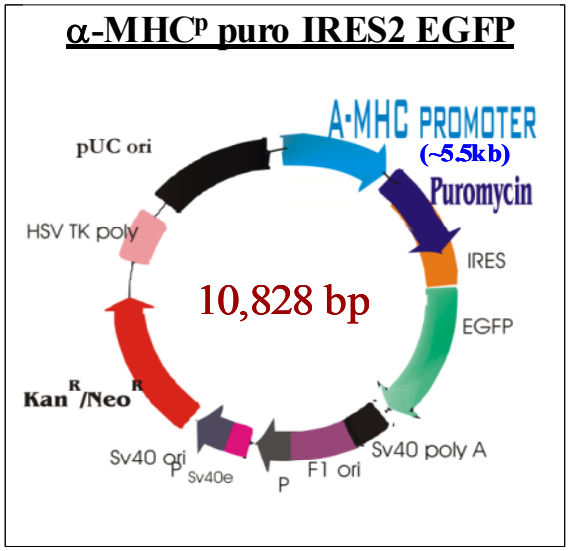

Figure 19 Plasmid map ofαMHC reporter ES cell targeting construct

Isolation of αMHC$^+$ cardiomyocytes

To induce differentiation, the hanging drop protocol was used. Briefly, an ES cell suspension of 2.5x10^4 cells per ml titer was prepared in IMDM supplemented with 20 % FCS, 1 % non-essential amino acids (vol/vol), 2 mM L-glutamine and 100 µM β-ME. 20 µl of this ES cell suspension was spotted on the inside of the upper lid of a 10cm bacteriological dish and then covered over its bottom dish containing 5 ml PBS. On day 2, the formed multicellular aggregates (EBs) were transferred to suspension in a new dish with 20 ml IMDM supplemented with 20% FCS, 1% non-essential amino acids (vol/vol), 2 mM L-glutamine and 100 µM β-ME. On day 8, contracting clusters were observed. At this stage, cultures were either treated with puromycin (4µg/ml) or left without treatment for 7 days with a medium change on every alternative day. On day 15, the beating clusters were trypsinised and used for FACS analysis or used for RNA extraction.

3.2.8 Patch clamp and sharp electrode electrophysiological studies

AP recordings were performed in single αMHC cardiomyocytes and in multicellular αMHC$^+$ cell aggregates at days 11-16. Single cardiomyocytes were obtained by dissociating puromycin-purified αMHC$^+$ cell aggregates using a protocol described before and incubated in DMEM + 20% FCS at 37°C and 5% CO_2 for 24-36 hours prior to the measurements. APs of spontaneously beating single αMHC$^+$ cardiomyocytes were measured by means of the whole-cell current-clamp technique using an EPC-9 amplifier and the PULSE software package (Heka Elektronik, Lambrecht, Germany). Patch clamp electrodes had a resistance of 3-4 MΩ when filled with intracellular solution containing (in mM) 50 KCl, 80 KAspartate, 1 $MgCl_2$, 3 MgATP, 10 EGTA and 10 HEPES, pH 7.4.

Spontaneous electrical activity of cardiomyocytes within plated □MHC$^+$ cell aggregates was assessed by conventional microelectrode recordings. The resistance of the sharp electrodes, which were filled with 3 M KCl, was 20-50 MΩ. Signals were acquired by a SEC-10LX amplifier (npi electronic, Tamm, Germany) connected to the PULSE software via the interface of the EPC-9.All experiments were performed at 37°C in standard extracellular solution containing (in mM) 140 NaCl, 5.4 KCl, 1.8 $CaCl_2$, 1 $MgCl_2$, 10 HEPES and 10 glucose or NaCl 136, KCl 5.4, NaH_2PO_4 0.33, $MgCl_2$ 1, glucose 10, hepes 5, $CaCl_2$ 1.8 (pH 7.4 adjusted with NaOH). All electrophysiological data were analyzed off-line with a custom made analysis software (kindly provided by Philipp Sasse).

3.2.9 Immunohistochemistry

One day prior to the sample processing, 50,000 cells per each well of Lab-Tek Permanox slide Chambers (Nalge Nunc International, USA) were seeded and cultured in the absence of puromycin. After 24 hours, the samples were fixed with 4% Paraformaldehyde or with –20 ^{0}C cooled methanol-acetone (1:1) solution, permeabilised with 0.1%Triton X-100, and labeled with the appropriate primary antibody in the optimal dilutions followed by labeling with the respective secondary antibodies. The specificity of the antibodies has been tested using the appropriate tissues and isotype control antibodies.

3.2.10 Sudan Red and Alizarin Red S stainings

The paraformaldehyde fixed samples were treated with Alizarin Red S for 5 minutes and then excess Alizarin Red was washed off by dipping in Aceteone: Xylene (1:1), followed by wash in Xylene. Then stained for haemtoxylin for 10 minutes and the excess dye was washed off in running water.

3.2.11 Semi-quantitative RT-PCR

Design of the RT-PCR primers

For the design of the primers, the online software “Primer3” was used. (http://frodo.wi.mit.edu/cgi-bin/primer3/primer3_www.cgi). Care is taken to choose the exon spanning primers to avoid the genomic DNA amplification. Primers with 23 bases and melting temperature around 60^0 C which give rise to amplicon sizes from 150-400 base pairs were preferred. Most of the Oligos were ordered from Metabion (Martinsried, Germany) and the rest from MWG (Ebersberg, Germany).

cDNA synthesis and PCR

Total RNA was extracted using RNeasy Mini Kit (Qiagen,Hilden,Germany) with on-Column DNase I (Qiagen) digestion according to the manufacturer’s instructions. 5μg total

RNA was reverse transcribed using SuperScript II Reverse transcriptase (Invitrogen) with random primers according to the manufacturer's recommended protocol. PCR amplification was done with REDTaq ReadyMix (Sigma) with 0.4μM each primer. GAPDH was used as an internal control. The following conditions were used. An initial denaturation at 95^0C for 2 minutes, followed by 22-35 cycles of 30 sec denaturation at 95^0C, 30 sec annealing at 60^0C and 60 seconds of elongation at 72^0. A final extension at 72^0C for 5 minutes was included. Electrophorectic separation of PCR products was carried out on 2% agarose gels with 0.001% Ethidium Bromide.

3.2.12 FACS analysis

Single cell suspension was prepared by trypsinisation. Cell clumps were removed by passing through cell strainer cap of round bottom tube from Falcon® (BD, Germany). Propidium Iodide staining (Sigma) was included to exclude dead cells. Acquisition of 10,000 live (PI negative) cells was made with FACScan (BD Biosciences) and the data analysis was done with CellQuest software (Becton Dickinson). The respective wild type EBs on the same day as the sample EBs were used as the control.

3.2.13 Affymetrix Hybridization

Total RNA was extracted from undifferentiated ES cells and EBs using the RNeasy total RNA isolation kit (Qiagen GmBH, Hilden, Germany). The preparation quality was assessed by agarose-formaldehyde gel electrophoresis. Three independent total RNA preparations, each 15 µg from the enriched specific lineages and the mixed cell population and from the undifferentiated ES cells were labeled with Target Labeling and Control Reagent package (Affymetrix) as described in the manufacturer's instructions. Briefly, double-stranded cDNA was synthesized using the one-cycle cDNA synthesis module. Biotinylated cRNA was synthesized with the IVT labeling kit and cleaned up using the sample cleanup module. After fragmenting of the cRNA for target preparation using the standard Affymetrix protocol, 15 µg fragmented cRNA was hybridized for 16 h at 45 °C to Mouse Genome 430 2.0 arrays which carry probes representing 45101 probe sets. Following hybridization arrays were washed and stained with streptavidin-phycoerythrin in the Affymetrix Fluidics Station 400 and further scanned using the Hewlett-Packard GeneArray Scanner G2500A. The image data were analyzed with GCOS 1.4 using Affymetrix default analysis settings and global scaling as normalization method. After RMA normalization [63] three pair-wise comparisons have been performed using the Student t-test (unpaired, assuming unequal variances). A Student t-test p-value < 10^{-2} and a fold change > 2 were used to identify and restrict the number of differentially expressed genes. For differentiation of treatment and developmental aspects hierarchical clustering of probe sets differential expressed between the three conditions in the F-test comparison (p-value cut off 10^{-7}; n = 617 probe sets) has been performed. The cluster analysis has been done using cluster version 2.11 [64] applying mean-centering and normalization of genes and arrays before average linkage clustering with uncentered correlation.

3.2.14 Affymetrix Analysis

DAVID functional annotation tool was used to classify the transcripts according to the Gene Ontologies. (http://david.abcc.ncifcrf.gov/summary.jsp). Hierarchical clustering was performed with Gene Cluster (Eisen et al. (1998) PNAS 95:14863).

3.2.15 Quantitative Real time PCR

Validation of the Affymetrix data was performed by quantitative real time PCR analysis with the ABI Prism 7900HT Sequence Detection System (Applied Biosystems, Foster City, CA). 100ng RNA was reverse transcribed with ThermoScript™ Reverse

Transcriptase (Invitrogen). Then Real time PCR was perfomed in triplicates for every sample using TaqMan Gene Expression Assays from Applied Biosystems (Foster City, CA). The Gene Expression Assays included for the validation were *Brachyury (T)* (Mm00436877_m1), *Sox17* (Mm00488363_m1), *αMHC* (Mm00440354_m1), *BMP-2* (Mm01340178_m1), *GAPDH*(Mm99999915_g1), and *Nanog* (Mm02019550_s1). Averaged C_t values of each qRT-PCR reaction from the target gene were normalised with the average C_t values of the housekeeping gene, *GAPDH,* that ran in the same reaction plate to get ΔC_t value . The fold change was calculated by using the formula, fold-change= $2^{-(\Delta C_t \text{ gene1} - \Delta C_t \text{ gene2})}$. ΔC_t of the gene in the sample in which it is expressed lowest is taken as ΔCt gene2 to calculate the fold change using the above formula. The resulting fold change is expressed as percentage of the maximum.

3.2.16 Episomal overexpression

For episomal overexpression studies, the original pMGD20 (a kind gift from Dr. M Gassmann) was linearised with *PvuI*, klenowed and blunt end ligated to EcoRI digested, klenowed pEF-1/Bsd vector (purchase from Invitrogen) to get pMGD20 Blasticidin. This plasmid encodes the polyoma large T antigen required for the episomal maintenance of the vector pPyCAGIP. T Brachyury clones were transfected with linearised pMGD20 Bsd with *NotI.* The novel transcripts cDNA clones were purchased from RZPD Deutsches Ressourcenzentrum fuer Genomforschung GmbH, Germany and geneservices, UK. The cDNAs were cloned in pPyCAGIP and the resulting overexpression plasmid was used to transfect the T Brachyury ES cells with lipofectamine 2000 transfection which are already transfected with pMGD20 Bsd. Stable clones were generated with puromycin selection and used for the experiments and the expression of the Large T antigen was checked by semi-quantitative PCR as shown in figure 20A.

3.2.17 siRNA Knock down

Optimization of siRNA delivery with Lipofectamine

The optimal amount of lipofectamine and optimal concentration of siRNA was determined using the siControl Reagent from Dharmacon. Positive control siRNA labeled with Rhodamine and targeted against Cycophilin B was used for the optimization. $1x10^5$CGR8 cells were plated 24 well dishes one day before transfection and were transfected with gradient amounts of Lipofectamine from 0.5μl to 1.5μl with different concentrations of siRNA for determining the optimal conditions. When increased the Lipofectamine amounts more than 1.5 μl, toxicity was observed to a greater extent. As shown in the figure 20B, 1.0μl Lipofectamine 2000and 100nm siRNA was found to be optimal, when performed in 24 well dishes. When transfected in 6 well plates, the amounts were linearly scaled up (4 fold) as recommended by Dharmacon.

4.Results and Discussion

4.1 EXPERIMENTAL DESIGN

For the isolation of mesodermal lineages and cardiomyocytes, the promoters of the following candidate genes were made use of to generate the respective stable ES cell lines with reporter (enhanced green fluorescent protein) and selection marker (puromycin resistance) under the control of the respective promoters.

1. *T-brachyury* ---Isolation of nascent mesodermal cells
2. *Bmp2* ---Isolation of late mesodermal cells
3. *αMyosin heavy chain* ---Isolation of cardiomyocytes.

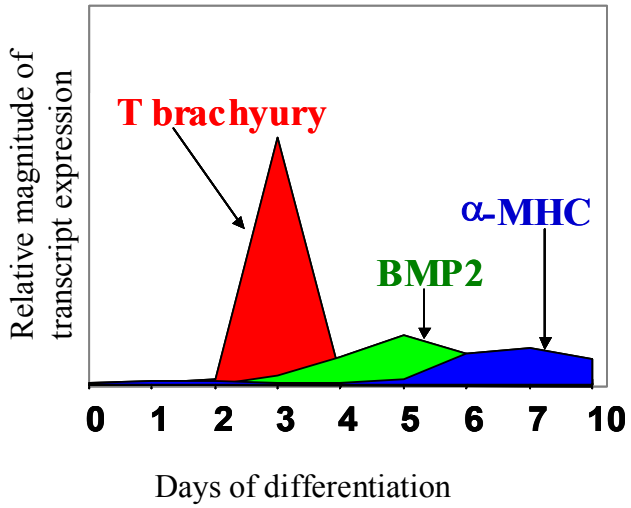

Figure 21 Expression patterns of the T Brachyury, BMP-2 and αMHC transcripts used for isolation of nascent mesoderm, late mesoderm and cardiomyocytes respectively during the course of differentiation, as obtained from microarray analysis.

Once the pure populations of mesodermal and cardiac cells were obtained, transcriptomic profiling of specific lineage cells were performed using microarrays. In addition, phenotypic analysis of the isolated cells was analyzed by immunohistochemistry and semi-quantitative PCR. Using bioinformatics approach, all the differentially expressed genes were analyzed. In the latter part, functional evaluation of the novel transcripts highly expressed in mesodermal cells but whose functions are still not yet annotated was done by using loss of function (siRNA mediated knock down) and gain of function (episomal over-expression) studies.

4.2 Transcriptomic profiling of wild type ES cells and differentiating EBs

ES cells are pluripotent and can give rise to any type of cells depending on the culture conditions. ES cells when maintained in the presence of adequate amount of LIF or cultivated on mouse embryonic fibroblasts remain in undifferentiated state and represents the inner cell mass of the blastula in the embryonic context.

When applied hanging drop protocol or placed in suspension in the absence of LIF, ES cells differentiate into 3 dimensional multicellular aggregates called Embryoid bodies. The mesoderm is established on day 3, the time point at which T Brachyury expression peaks high. The first contracting cardiomyocytes are observed on day 7 onwards. For the selective lineage of any mesodermal cells, either the formation of more mesodermal cells should be favoured at the expense of other germ layers or the differentiation of mesoderm into the lineage of choice should be enhanced at the expense of other mesodermal lineages. Till date, the mechanisms of mesoderm development and other germ layers development remain still elusive.

In order to better understand the molecular mechanism of germ layer development and their lineage commitment, a large scale transcriptomic profiling of undifferentiated embryonic stem cells and the differentiating EBs at daily intervals over a period of 10days, the latest time point at which the onset of cardiomyogenesis is complete, was performed as a first step towards characterizing the pure mesodermal and cardiac population. The morphologies of the embryonic stem cells and the differentiating EBs are shown in the Figure 22. We used feeder layer free embryonic stem cell line CGR8 and “Hanging drop protocol” as outlined in section (3.2.6) to obtain more reliable and reproducible experimental results. The differentiation of embryonic stem cells is stage specific. Establishment of ectoderm precedes mesoderm formation and occurs between day 0-3. Establishment of mesoderm and definitive endoderm occurs 2 days onward and 3days onwards respectively. Thus the germ layer development from ES cells mimics the embryonic development sequentially (Figure 23).

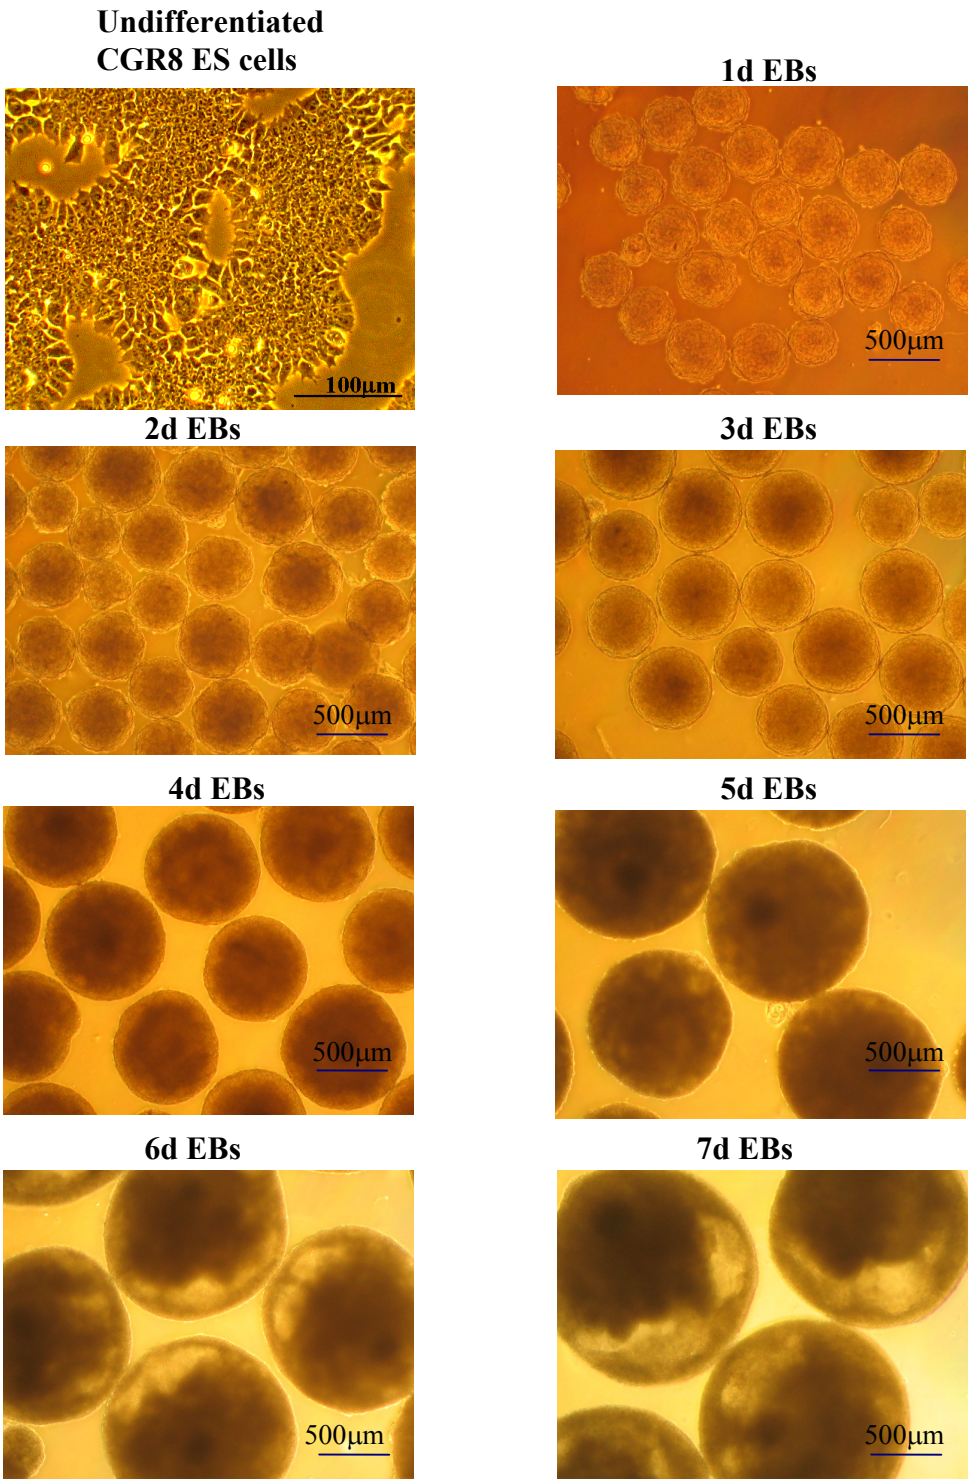

Figure 22: Morphologies of the differentiating EBs on daily intervals. Cavitation occurs in the same way as in the in vivo embryonic development, starting from day 5 at which time point BMP-2 is expressed at its peak and is postulated to be the initiator of cavitation by its apoptotic property.

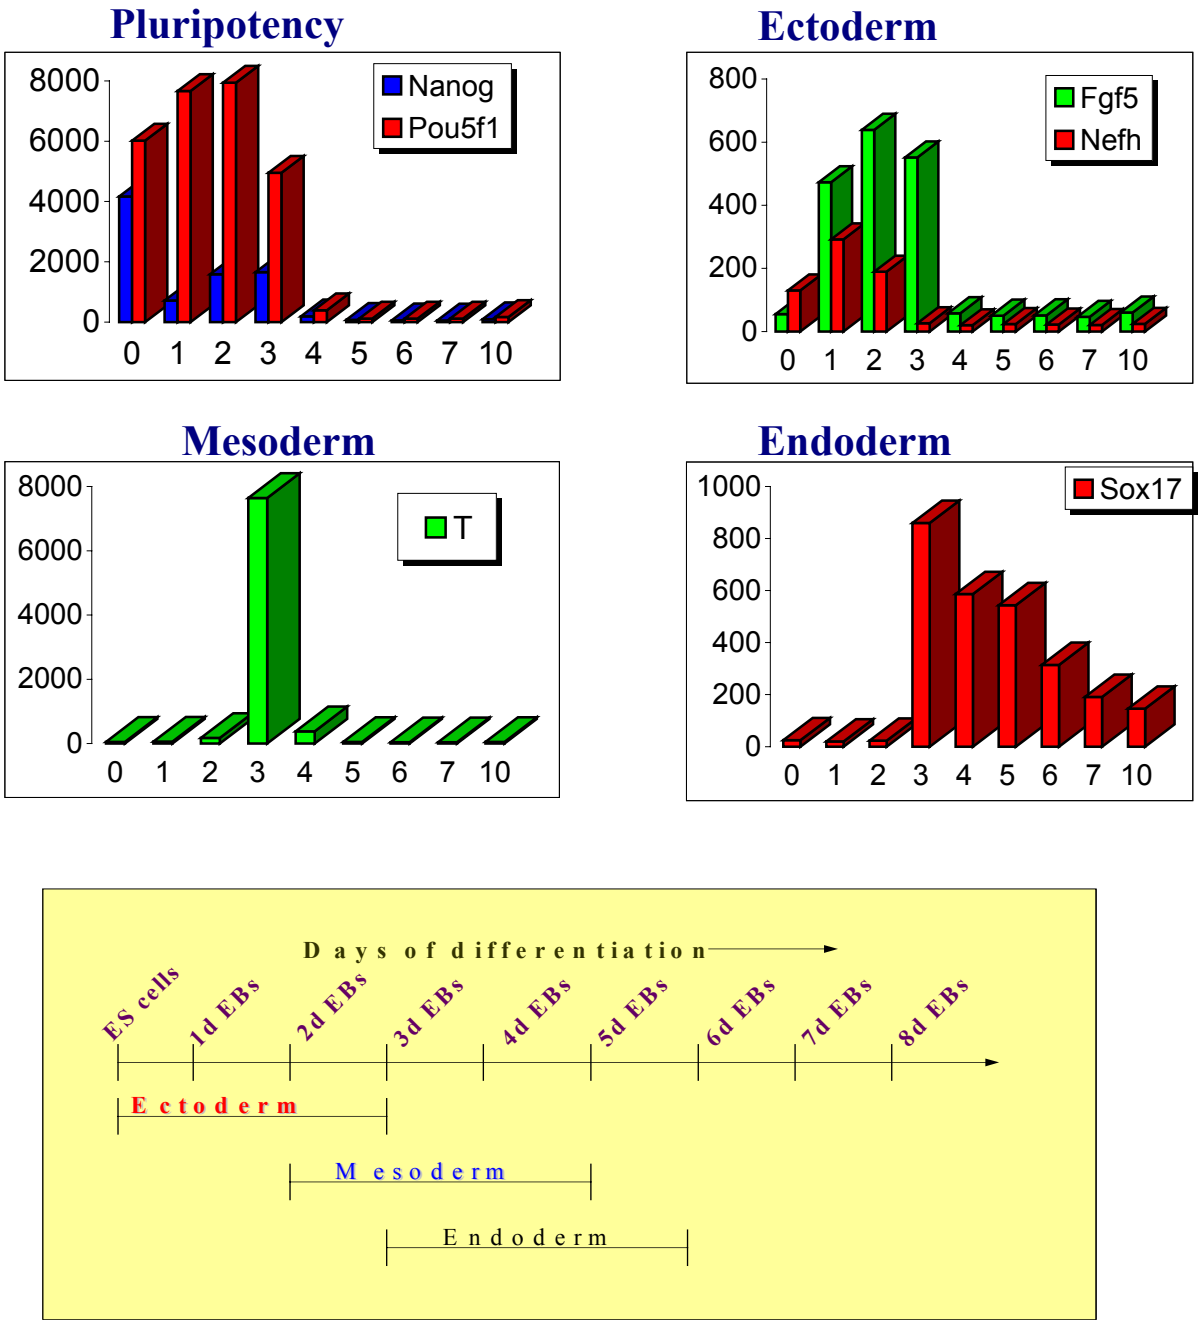

Figure 23 Stages of germ layer formation during embryonic stem cell differentiation. *Nanog* and *Pou5f1* are the markers for pluripotent stem cells, *Fgf5* , marker for primitive ectoderm, Neurofilament heavy(*Nefh*), marker for ectodermal lineages, *T Brachyury*, a pan-marker for nascent mesoderm and *Sox17*, pan marker for definitive endoderm. The values on Y axis represent the relative magnitude of expression.

4.2.1 Validation of the Affymetrix data by Real Time PCR Quantitation

The affymetrix data obtained from the ES cells and the differentiating EBs were verified by quantitative real time PCR analysis of the pluripotent and germ layer specific genes –*Nanog, T- Brachyury, Bmp-2, Neurofilament H, Sox 17* and α- myosin heavy chain. As seen in the figure 24, the Real time PCR data correlated very well with the affymetrix data.

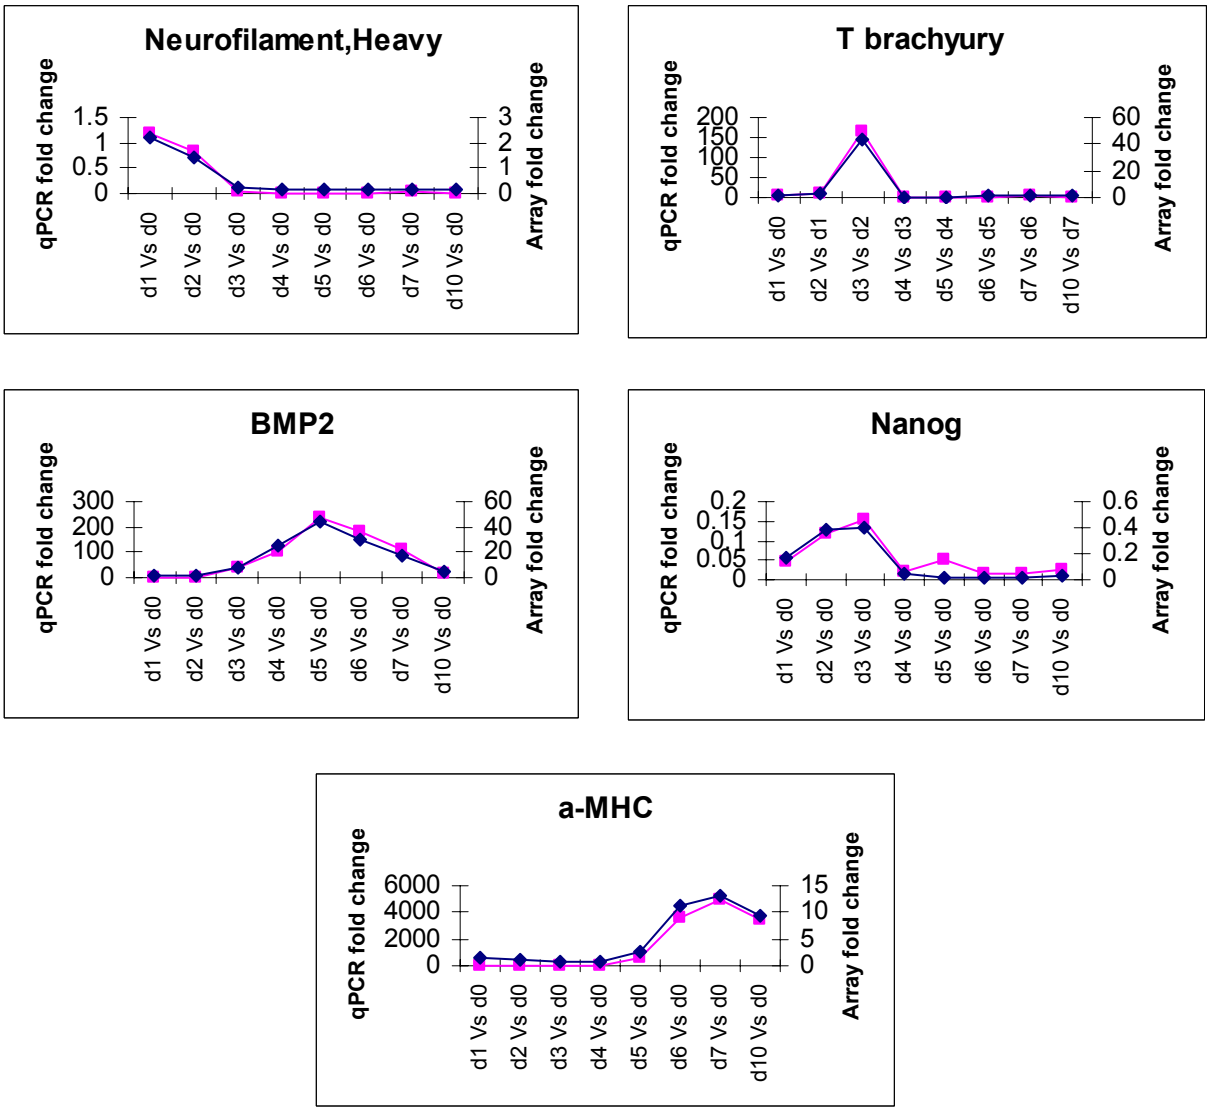

Figure 24 Validation of the affymetrix results by qPCR. The fold change was calculated by using the formula, fold-change = $2^{-(\Delta C_t \text{ gene1} - \Delta C_t \text{ gene2})}$. ΔC_t of the gene in the sample in which it is expressed lowest is taken as ΔCt gene2 to calculate the fold change using the above formula. The pink line represent results from quantitative PCR and the blue line from affymetrix data.

4.3 CHARACTERIZATION OF T-BRACHYURY^{+} MESODERMAL POPULATION

In the mouse embryo, mesoderm is generated from the epiblast or embryonic ectoderm through the process of gastrulation that is initiated at approximately day 6.5 of gestation (for review see [10]). At the onset of gastrulation, the epiblast cells in the region that defines the posterior part of the embryo undergo an epithelial to mesenchymal transition and form a transient structure known as the primitive streak from which the mesoderm emerges. The newly formed mesoderm migrates away from the primitive streak, moves laterally and anteriorly and is patterned into various populations with distinct developmental fates. Brachyury is expressed in all nascent mesoderm and downregulated as these cells undergo patterning and specification into the derivative tissues including skeletal muscle, cardiac muscle and connective tissues in addition to blood and endothelium[27,65]. In the ES/EB model system, mesoderm, as defined by expression of the T-box gene Brachyury, is induced within 48 hours of the onset of differentiation and persists until day 4 (Figure 25). To visualize and to isolate these short lived nascent mesodermal cells which are at the very beginning of patterning, we generated transgenic ES cell clones transfected with a plasmid construct in which T Brachyury promoter (4.5kb) drives the expression of both EGFP and puromycin resistance cassettes bicistronically with the help of an IRES element.

4.3.1 Generation and analysis of the T-brachyury ES cell clone

Stable T-Brachyury clones were generated by electroporation with linearised pTbra^{p} IRES2 EGFP construct with neomycin selection. Embryoid Bodies, when made from the T-brachyury ES cell clone by hanging drop protocol and analyzed at regular intervals, showed the transient expression of T-brachyury transcripts as shown by RT-PCR in figure 25a. FACS analysis of the EBs showed the same pattern of EGFP expression as the transcript expression (Figure 25D). The ES cells and EBs from this transgenic clone behaved faithfully with the wild type ES and EBs. The T-brachyury expression is distributed uniformly throughout the EBs as evident from the EGFP expression in every EB (Figure 25C).

4.3.2 Isolation and Transcriptomic Profiling T-brachyury^{+} population

On day 0, EBs were made from T-brachyury ES (CGR8) cell line by hanging drop protocol. On second day, the hanging drops EBs were transferred into suspension. On third day, the EBs were treated or untreated with puromycin at a concentration of 5ug/ml for 2 days. On 5th day, the medium was changed and added medium with or without puromycin at a concentration of 2μg/ml for 1 day. On day 6th , RNA was isolated from EBs treated or untreated with puromycin for affymetrix analysis. Application of puromycin led to the enrichment of the T-brachyury cells up to 79% (Figure 26). The puromycin resistant T-

brachyury population along with the undifferentiated ES cells from the T-brachyury ES cell clone and the control 6day EBs without puromycin treatment were included for transcriptomic profiling.

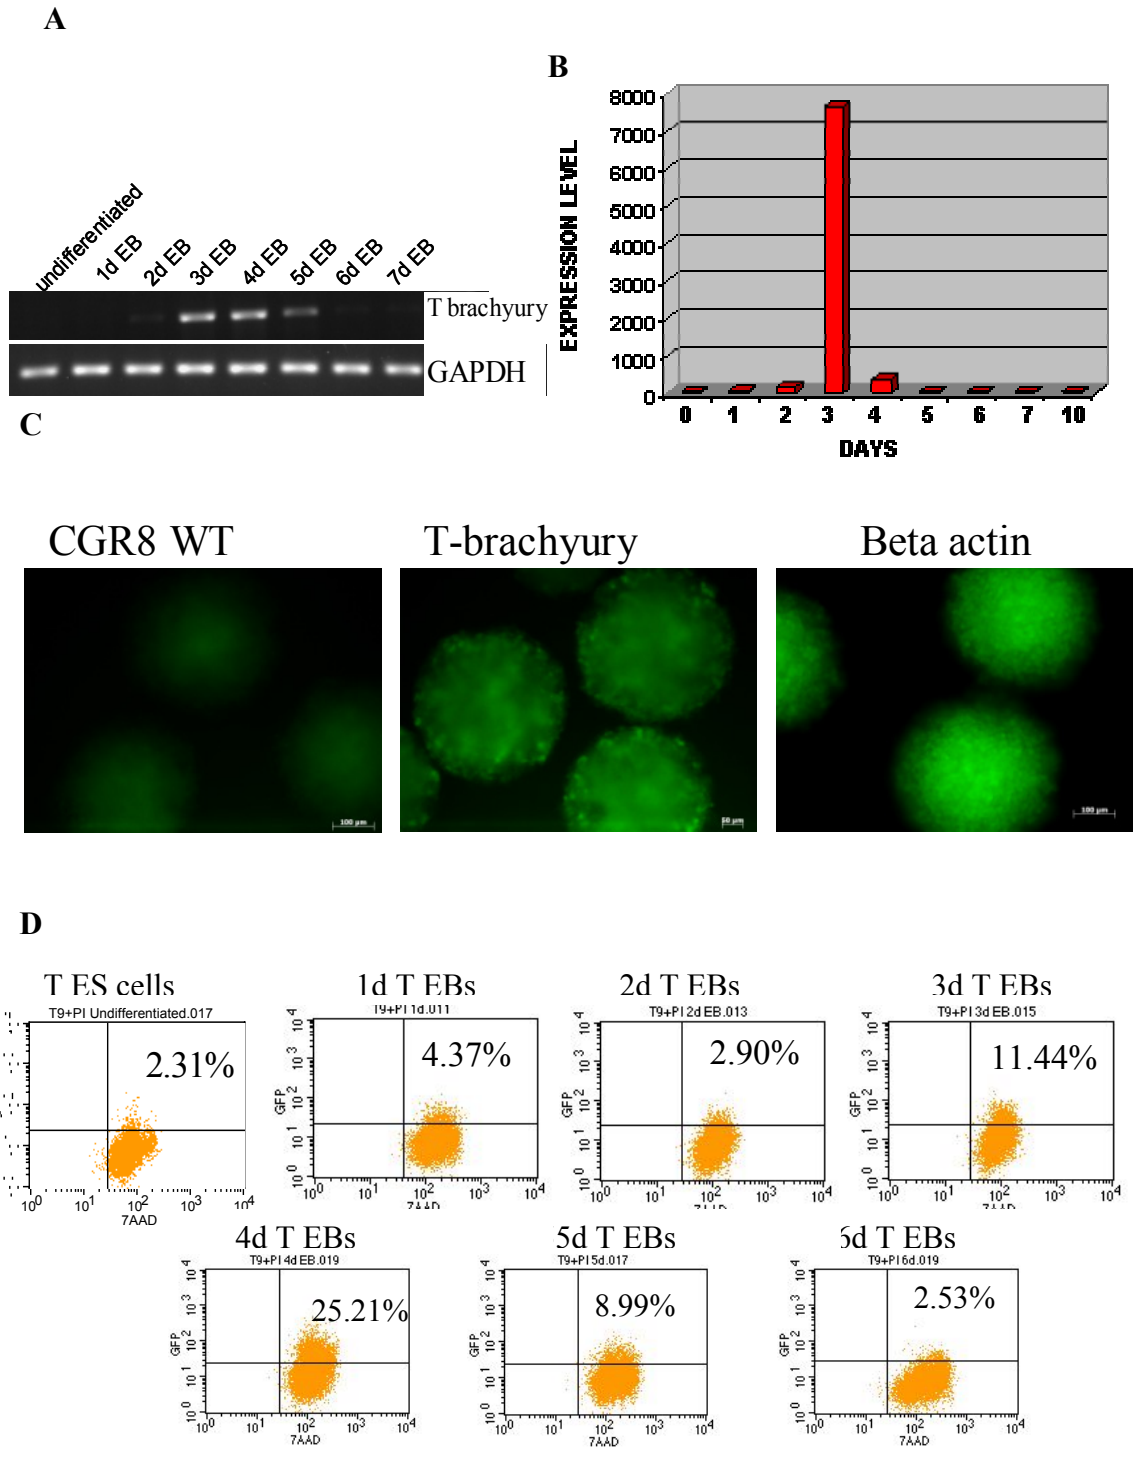

Figure 25 A) Semi quantitative RT-PCR analysis of T Brachyury transcript expression in ES cells and differentiating wild type EBs. B). Affymetrix analysis of the T Brachyury transcript expression in ES cells and in differentiating wild type EBs. C) Fluorescence microscopic pictures of 4-day-old EBs from CGR8 wild type, T Brachyury clone, and β actin clone. The latter expressed GFP ubiquitously. The intensity of green fluorescence emitted by Brachyury EBs very low compared to the strong (βactin) promoter driven EGFP. D) FACS analysis of fluorescence emission by Brachyury ES cells and EBs during the course of differentiation, as an index of T-brachyury expression.

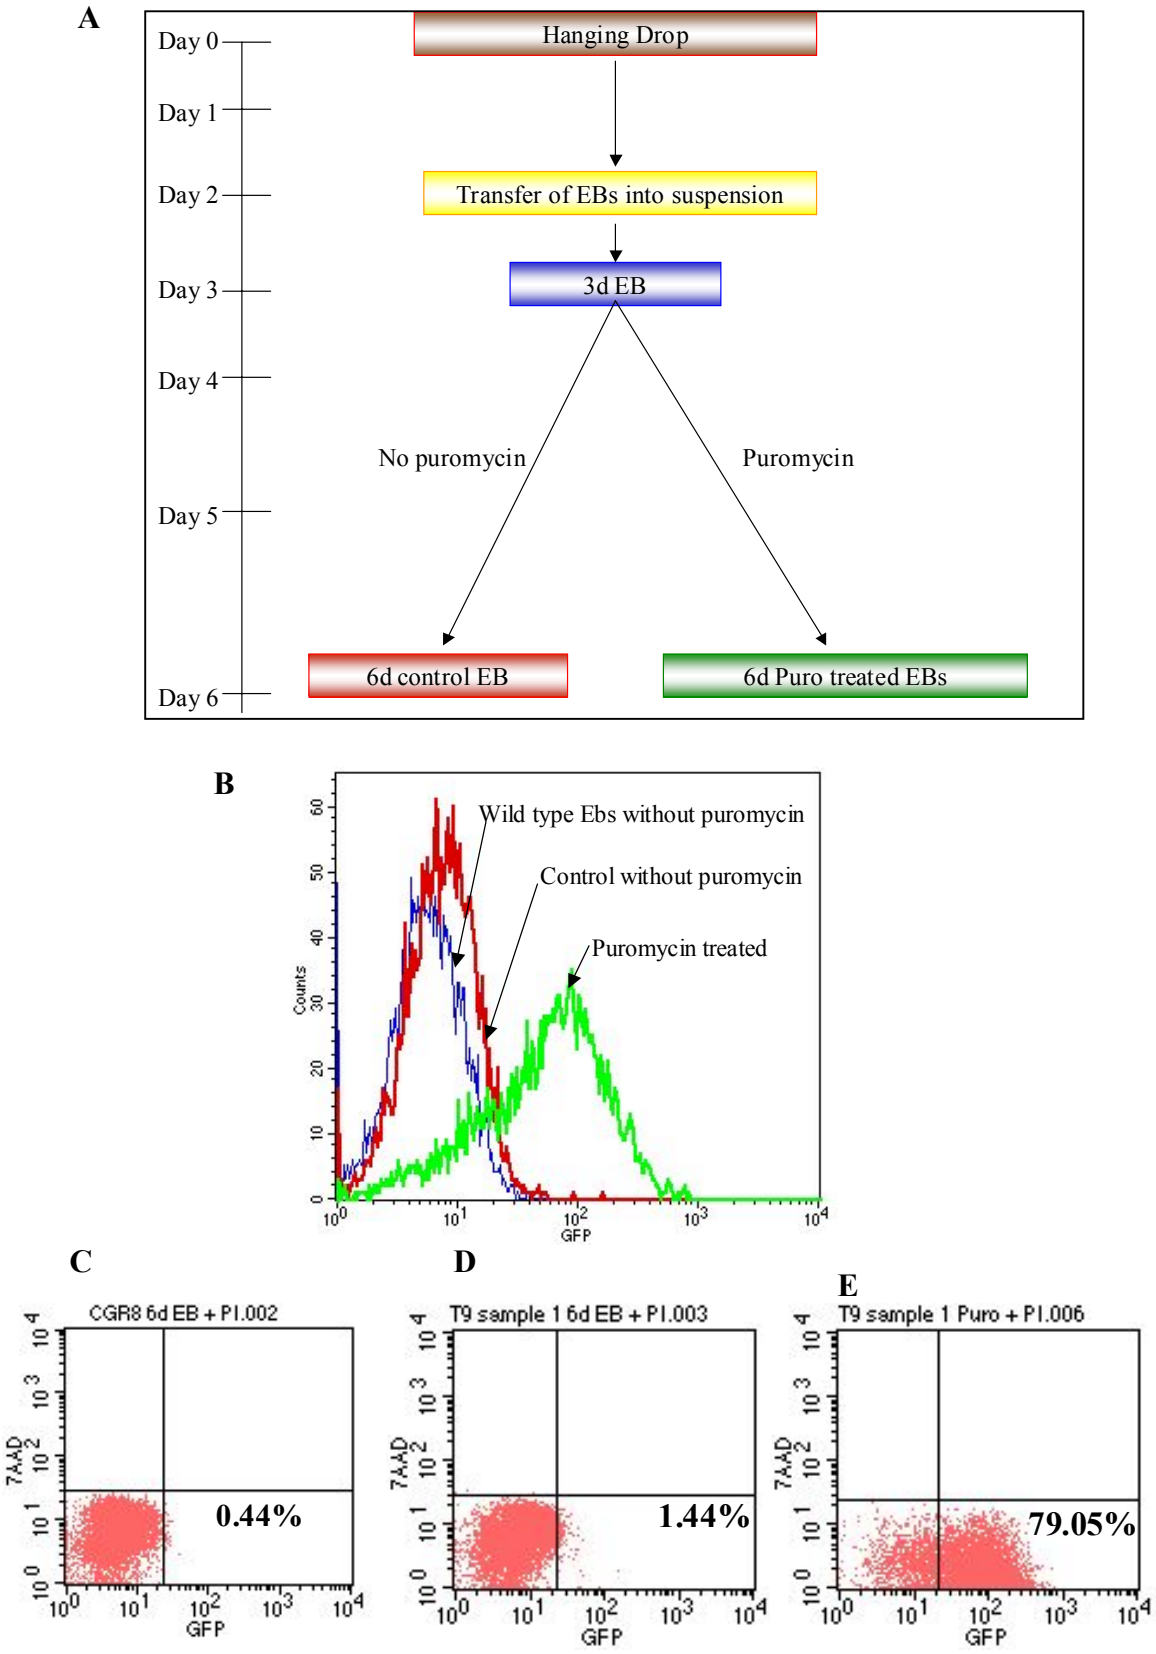

Figure 26 A) Schematic outline of the protocol for the enrichment of T Brachyury population by puromycin selection. B, C, D and E). The purity of the T-brachyury population obtained by the protocol (A) as assessed by FACS analysis.

4.3.3 Validation of Affymetrix data by quantitative real time PCR

The affymetrix data obtained from the ES cells, puromycin treated 6day EBs (T-brachyury^{+} cell population and puromycin untreated 6 day EBs) were verified by quantitative real time PCR analysis of the pluripotent and germ layer specific genes –Nanog, T-Brachyury, BMP-2, Neurofilament H, Sox 17 and α- myosin heavy chain. As seen in the figure 27, the Real time PCR data correlated very well with the affymetrix data.

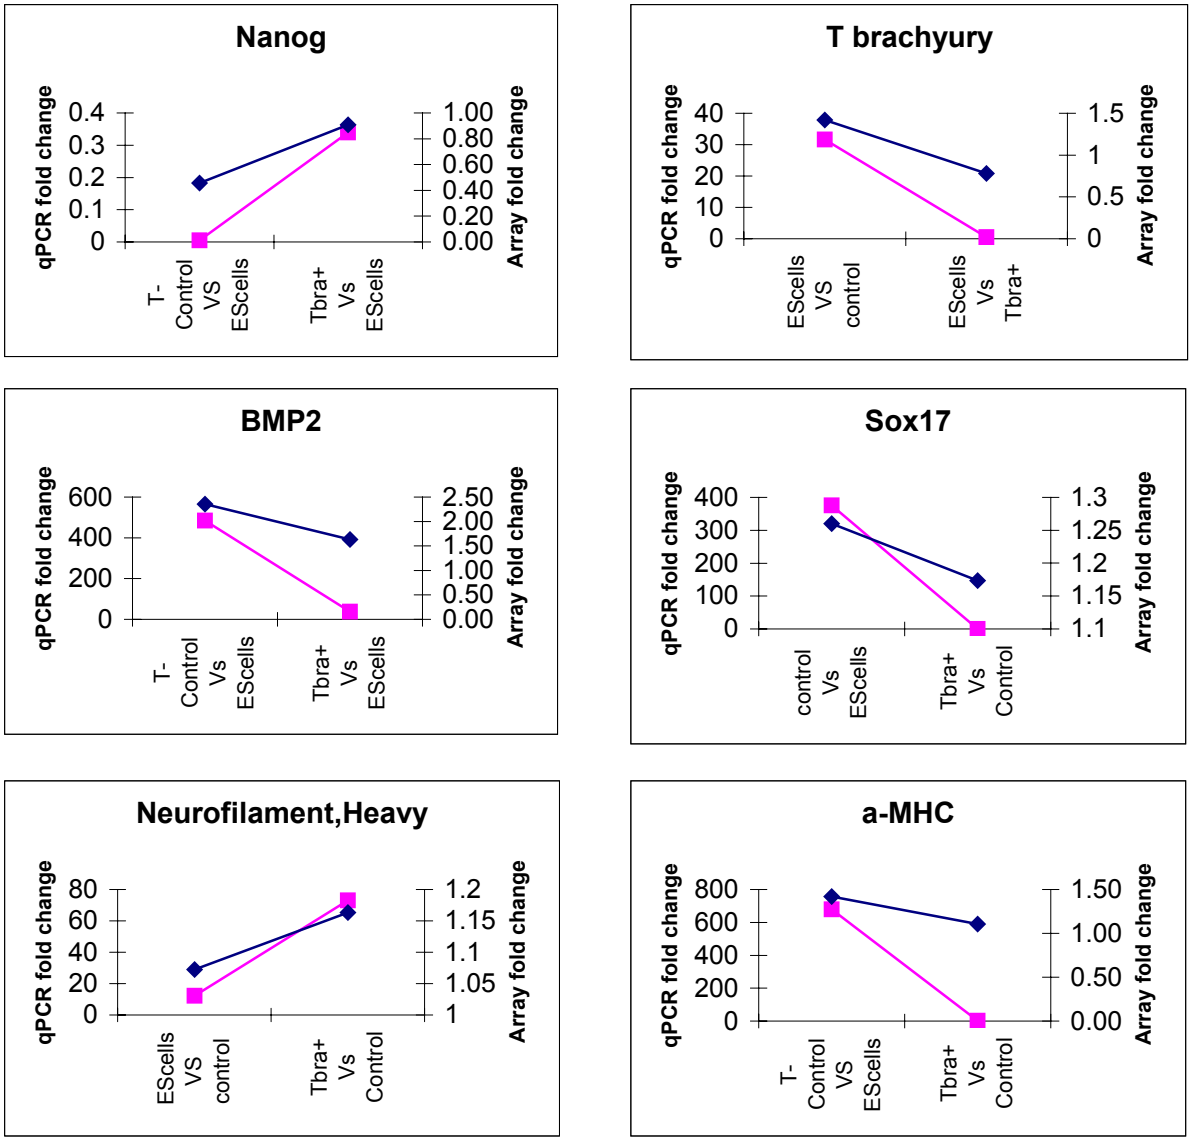

Figure 27. Validation of the affymetrix results by qPCR. The fold change was calculated by using the formula, fold-change = $2^{-(\Delta C_t \text{ gene1} - \Delta C_t \text{ gene2})}$. ΔC_t of the gene in the sample in which it is expressed lowest is taken as ΔCt gene2 to calculate the fold change using the above formula. The pink line represent results from quantitative PCR and the blue line from affymetrix data.

4.3.4 Affymetrix analysis of the transcriptome of T-brachyury$^+$ population

To rule out the differentially expressed transcripts are specific to T-brachyury cells and are not due to the puromycin application, transgenic β actin clones were generated in the same way like the T-brachyury clones except that the βactin promoter in the place of T-brachyury was used to serve as puromycin treatment controls. There were 6 unique transcripts with student t-test value of $p<0.01$ differentially expressed between puromycin treated 7day β actin EBs and untreated β actin EBs (as discussed for BMP-2 transcriptome analysis in the next chapter) and were excluded from the analysis. Thereafter the transcriptomic analysis was performed as follows.

4.3.4.1 Major pathways / biological processes differentially regulated in T Brachyury cells

Overall, there are 5616 unique transcripts differentially expressed (2 fold up or 2 fold down with an ANOVA p value cut off of less than 0.01) compared to either the T Brachyury ES cells or 6day old control EBs (i.e., the intersection of all differentially expressed genes in T Brachyury population in comparison to at least one of either the ES cells or 6day EBs. Among these transcripts, 711 transcripts are participating in pathways and 723 genes are implicated in embryonic development as shown in figure 28. Strikingly 95 transcripts participate in MAPK signaling pathway, 54 transcripts in Wnt Signaling and 41 transcripts in TGFβ signaling pathways (Figure 28). The differential expression of these transcripts in each pathway is summarized in figures 29,30and 31. Most of the rest transcripts take part in metabolism and a significant number of them in cell cycle, p53 signaling pathway, focal adhesion and axon guidance as shown in annexure 1.

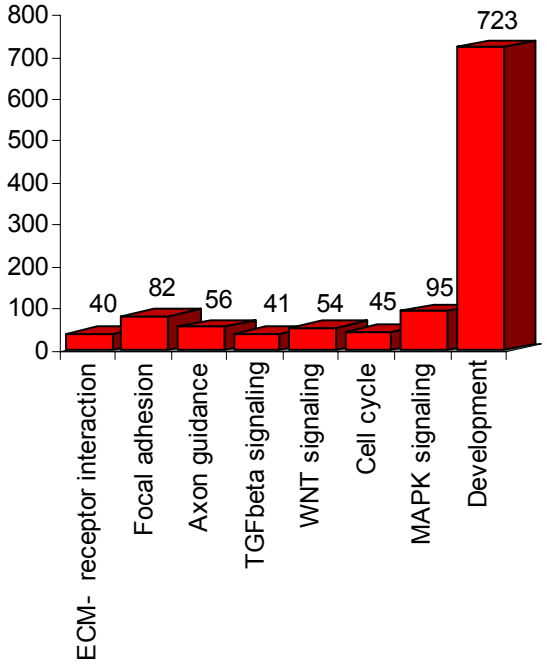

Figure 28. An overview of the number of transcripts differentially expressed in T brachyury population according to different Gene Ontologies(GOs), as obtained from DAVID analysis.

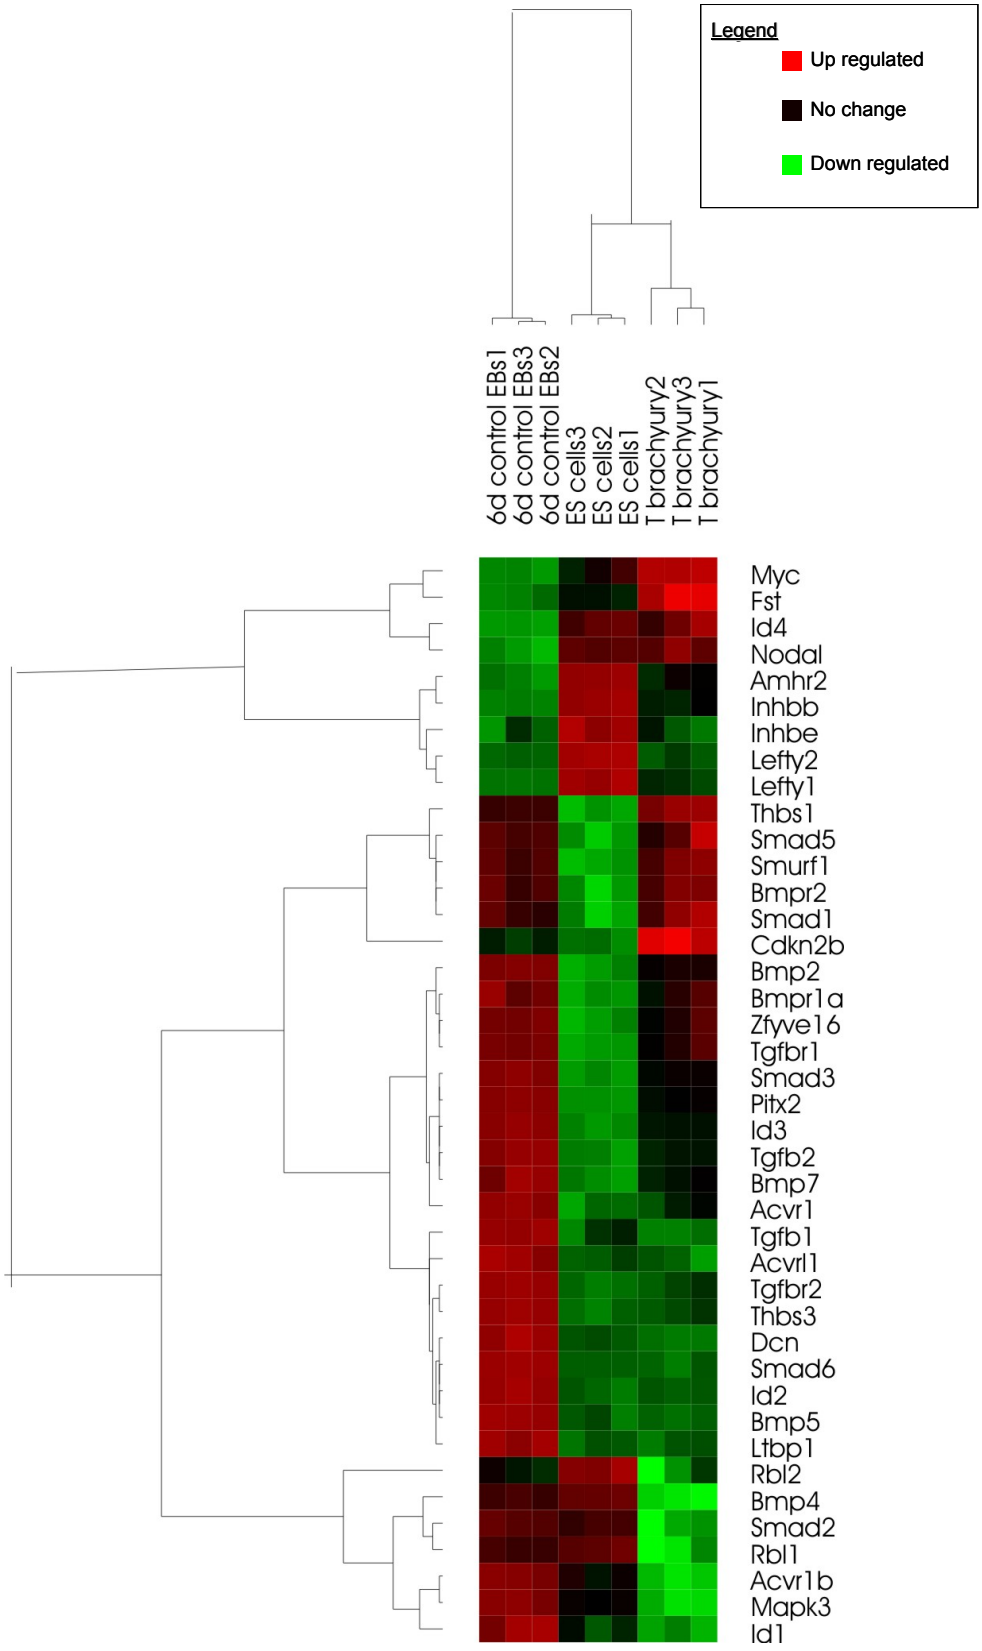

Figure 29. Hierarchical clustering of the transcripts differentially expressed in T-brachyury^{+} cells that participate in TGF β signaling pathway

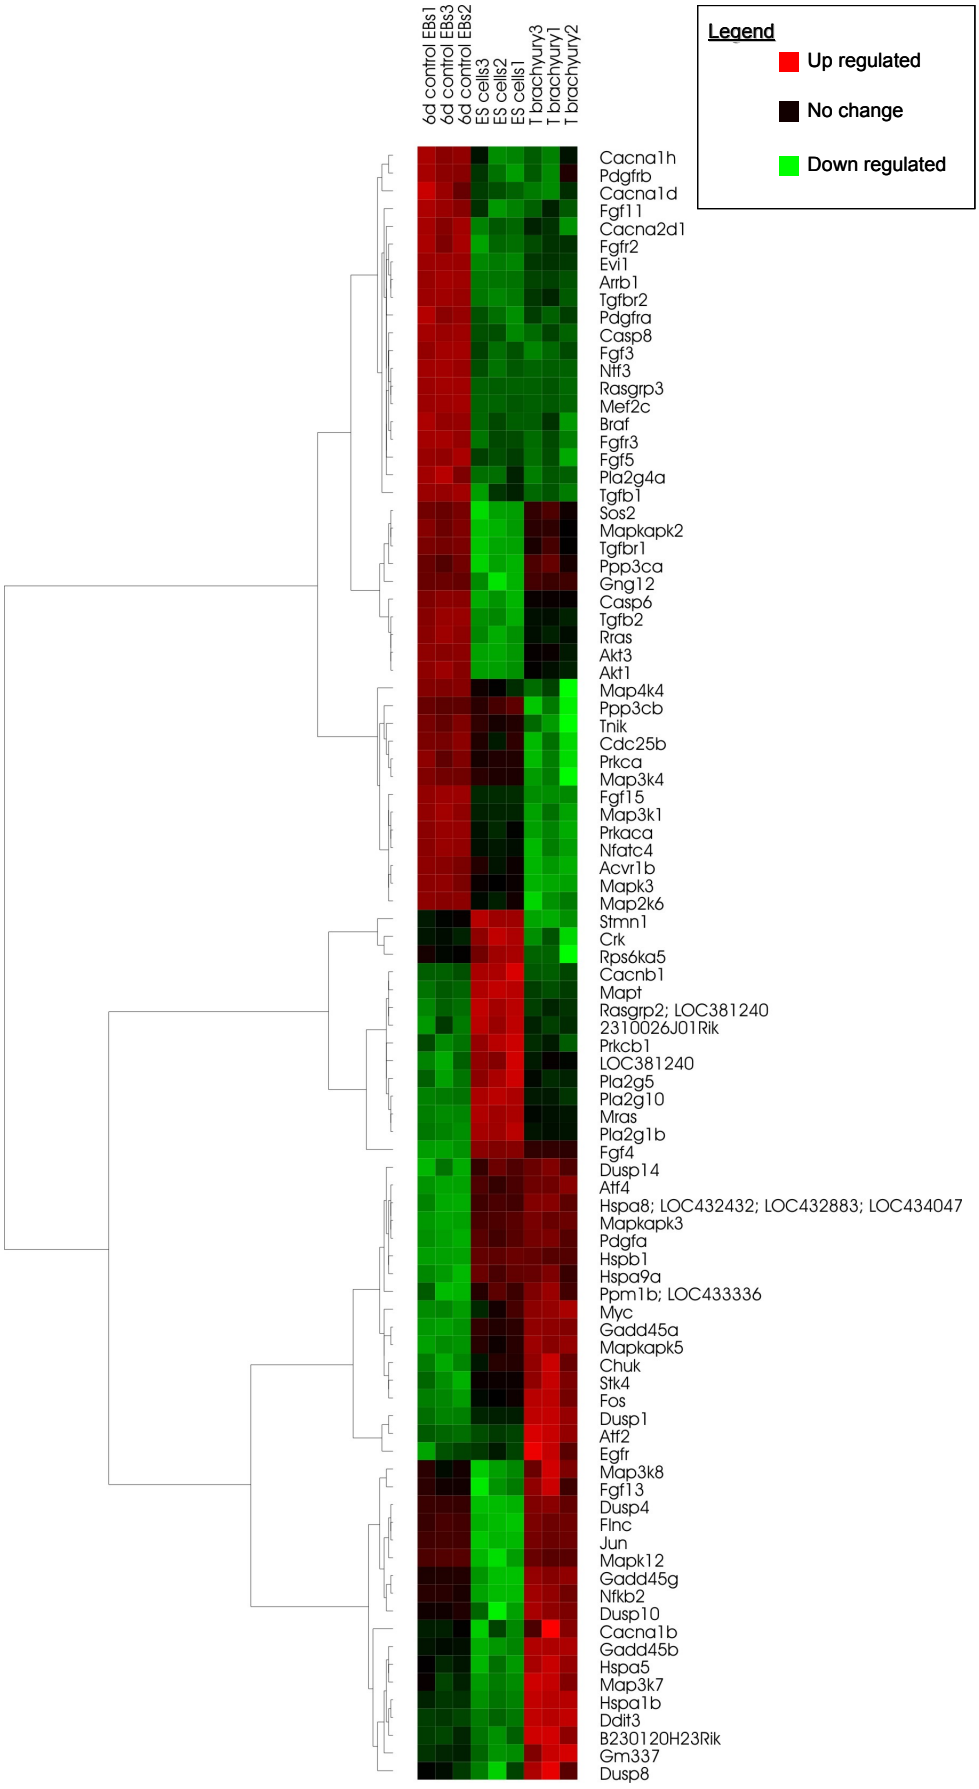

Figure 30. Hierarchical clustering of the transcripts differentially expressed in T brachyury^{+} cells that participate in MAPK signaling pathway

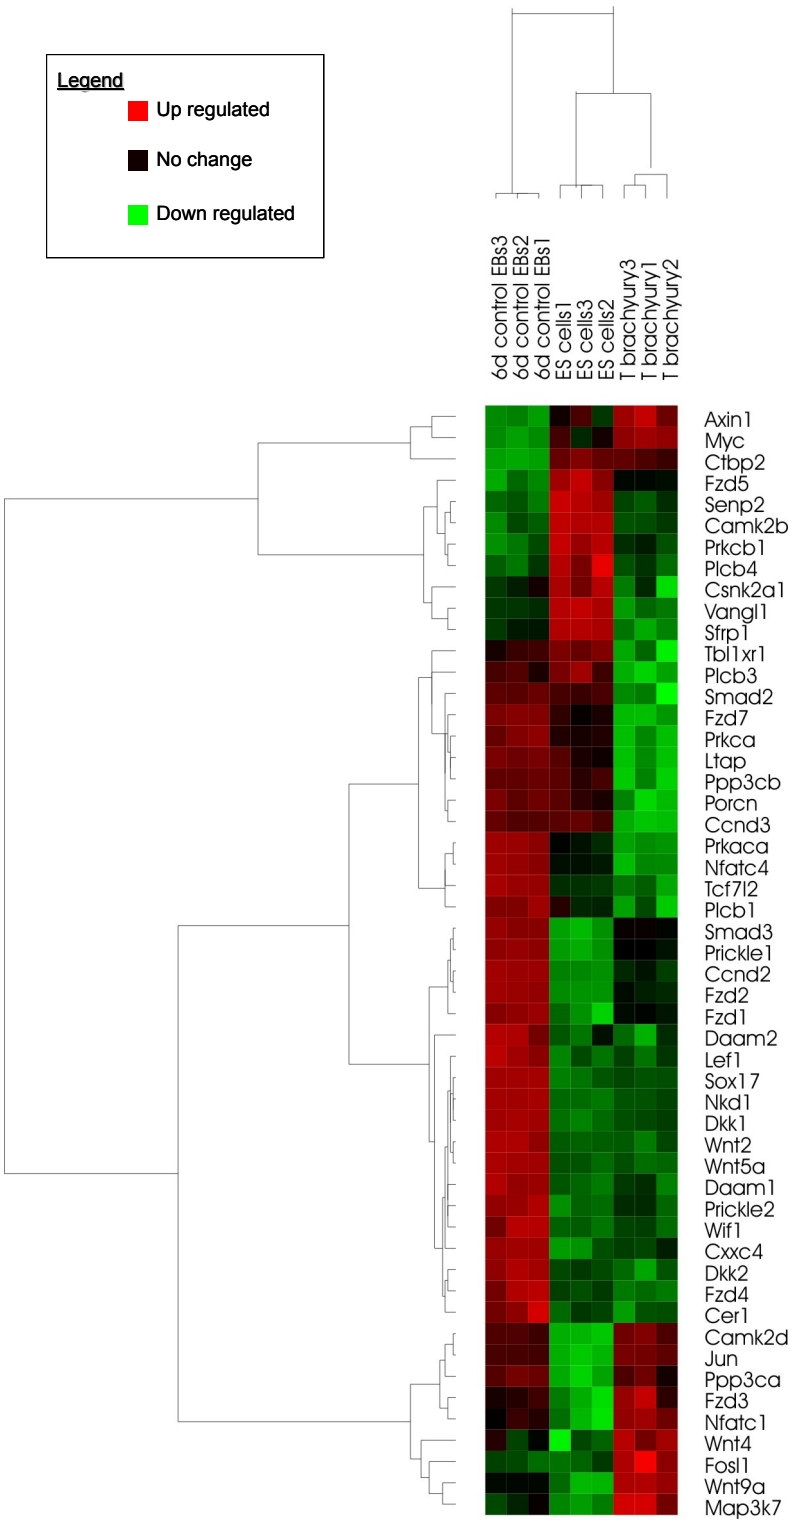

Figure 31. Hierarchical clustering of the transcripts differentially expressed in T brachyury^{+} cells that participate in Wnt signaling pathway

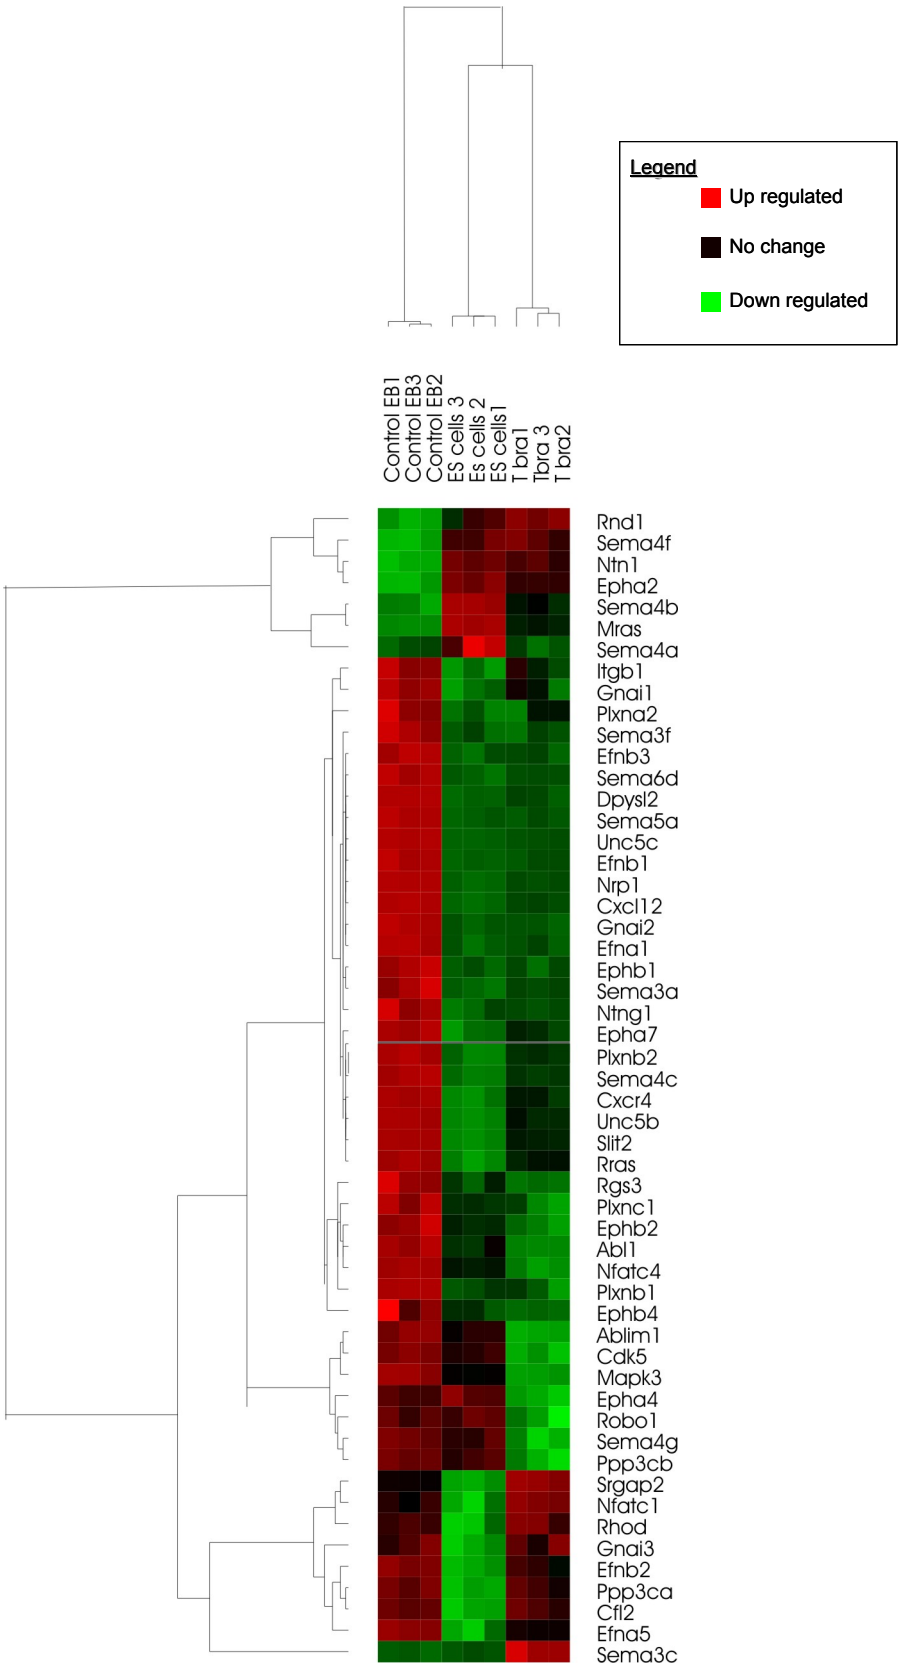

Figure 32. Hierarchical clustering of the transcripts differentially expressed in T Brachyury cells that involve in axon guidance.

This shows that the T Brachyury population has several dynamically ongoing functional signaling cascades, which are implicated to play a crucial role in early embryonic patterning. The transcripts involved in axon guidance are almost down regulated indicating the transition of primitive ectoderm into mesoderm and development of neuronal phenotypes in the control but not in T Brachyury population (Figure 32).

4.3.4.2 Classification of differentially expressed transcripts in T Brachyury in comparison to ES cells and 6day control EBs

T Brachyury population is a transient one during differentiation under normal conditions and needs co-operation from other 2 germ layers for the further lineage commitment. When they were kept in isolation from the other germ layers, their interaction with the other germ layers is eliminated and hence they slow down in terms of the differentiation and remain in differentiation state between the starting ES cell state and the 6d control EBs which, are far advanced in terms of differentiation due their intact interaction with the other 2 germ layers. Hence characterization of differentially expressed transcriptome of T Brachyury population needs to be compared with both the T ES cells and 6d Control EBs. Thus the analysis will need to be addressed as follows.

1. *Upregulated in T Brachyury$^+$ cells than both ES ells and 6day control EBs*
    i. Uniquely upregulated in T Brachyury cells (Not Differentially expressed in ES cells Vs 6day EBs)
    ii. Not Uniquely expressed in T Brachyury cells (Differentially expressed in ES Vs 6d EBs)
2. *Downregulated in T Brachyury$^+$ than both ES ells and 6day control EBs*
    i. Uniquely downregulated in T Brachyury cells (Not Differentially expressed in ES cells Vs 6day EBs)
    ii. Not Uniquely expressed in T Brachyury cells (Differentially expressed in ES versus 6d EBs)
3. *Upregulated in T Brachyury$^+$ than ES cells but downregulated than 6d control EBs*
4. *Upregulated in T Brachyury$^+$ than 6d control EBs but downregulated than ES cells*

Analysis of upregulated transcripts in T Brachyury$^+$ cells in comparison to both ES cells and 6day EBs.

There are 427 transcripts upregulated in T Brachyury cells in comparison to both ES cells and 6day old control EBs. Among them, there are 342 transcripts, which do not show any differential expression among ES cells and 6day EBs. The other 85 transcripts even though are upregulated compared to both ES cells and 6day EBs, they in turn show differential expression among ES cells and EBs. The distribution of the transcripts according to Gene Ontology "Biological Process" as analyzed with David functional annotation tool is presented in the Figure 33. The 393 transcripts upregulated uniquely in T Brachyury cells but not in ES VS EBs are the bona fide transcriptomic signatures of T Brachyury$^+$ mesodermal cells. There are 42 T Brachyury cell specific transcripts involved in development according DAVID analysis and are enlisted in table 1. The unique T Brachyury cell specific transcription factors and the transcripts involved in signaling and development are enlisted in tables 2 and table 3. The rest transcripts are represented by more than one Gene ontologies and are shown as heat map in annexure 2. Among the transcripts upregulated in T Brachyury cells that in turn showed differential expression in ES cells Vs EBs, there are 18 transcripts involved in developmental processes and are listed in the annexure 3.

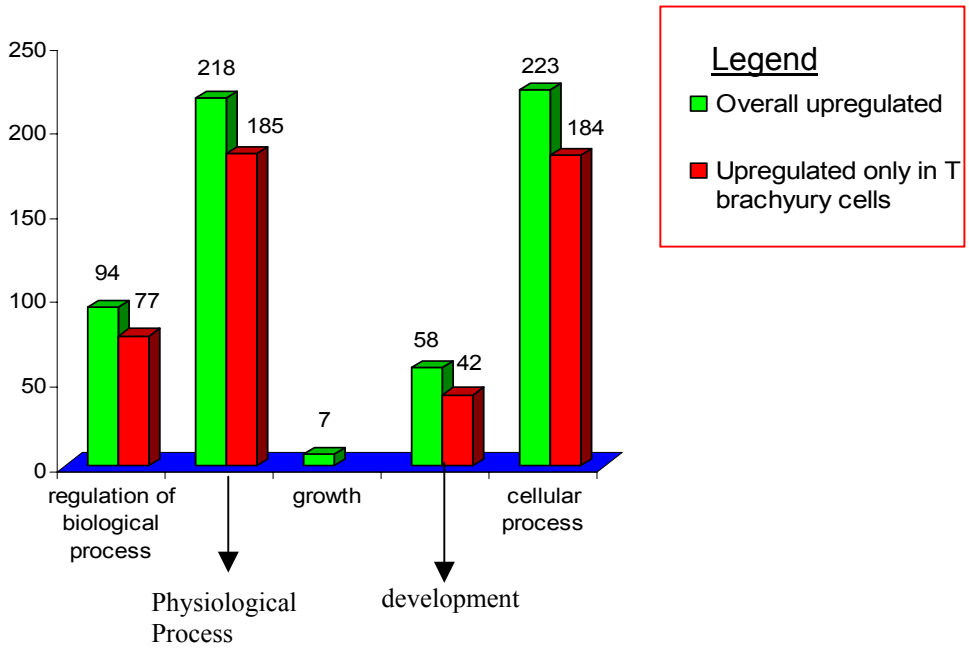

Figure 33. Transcripts upregulated more than both ES cells and control EBs according to the biological processes. A) All transcripts which are upregulated in T Brachyury cells than both ES cells and 6 day control EBs. B) The T Brachyury cell specific unique transcriptome that does not show differential expression between ES cells Vs 6 day EBs but show up-regulation in T Brachyury cells than both ES cells and EBs.

Table. 1a The development related transcripts specifically upregulated in T Brachyury population. The fold change is expressed relative to the lowest value of expression that is normalized to be 1.

2. Downregulated in T Brachyury than both ES cells and 6day control EBs

There are 411 unique transcripts downregulated in T Brachyury cells than both ES cells and 6day control EBs. Of them, there are 338 transcripts uniquely downregulated in T Brachyury cells (these do not show any differential expression among ES cells and 6day EBs). Among them, the developmental related transcripts and transcription factors are listed in the annexures 4 and 5. Apart from that, 73 transcripts are downregulated in T Brachyury cells compared to both ES cells and 6day EBs, which in turn show differential expression among ES cells and EBs and some of them are GTPase regulators and 9 others are related to development as listed in annexure 6A and B.

3. Upregulated in T Brachyury^{+} cells than ES cells but downregulated than 6day old control EBs

256 unique transcripts were found to be upregulated in T Brachyury cells compared to ES cells but down regulated in comparison to 6day control EBs. Among them, 5 transcripts are involved in TGF β signaling pathway and they are - MAD homolog 3, Paired-like homeodomain transcription factor 2, Transforming growth factorβ2, *BMP-2* and inhibitor of DNA binding 3. Interestingly the Id protein and Pitx2 are upregulated to direct mesoderm specification. There are 6 transcripts which play a role in Wnt signaling pathway are MAD homolog 3, Prickle like 1 (DROSOPHILA), SRY-BOX containing gene 17 (Sox17), Frizzled homolog 1, Cyclin D2 and Frizzled homolog 2. Sox17 is early marker for endoderm. Apparently, the transcript is present in the T-brachyury population indicating the existence of mesendoderm as already reported by several groups. Kubo and his colleagues used brachyury (T) as a marker for primitive streak mesoderm and showed that T-GFP-expressing cells in ES cell cultures could give rise to cells expressing endodermal markers[66]. Among the 256 transcripts, 45 transcripts are developmentally important genes as shown in the annexure 7.

4. The transcripts upregulated in T Brachyury cells than 6d control EBs but downregulated than ES cells.

There are 225 unique transcripts, which are upregulated in T Brachyury^{+} cells compared to 6day EBs but downregulated in comparison to ES cells. The development related transcripts and transcription factors are shown in annexures 8 and 9. It is interesting to note that the transcripts Oct4 and Fgf4 are upregulated in T Brachyury cells compared to the control EBs.

4.4 CHARACTERIZATION OF BMP-2$^+$ MESODERMAL POPULATION

BMP-2, the late mesodermal marker and a member of TGF-beta superfamily, plays a crucial role in early embryonic patterning as evidenced from gene-ablation studies[67,68]. Its expression immediately follows the transient expression of T-Brachyury in the nascent mesoderm. It is expressed normally in lateral plate mesoderm and extra embryonic mesoderm[67,69]. BMP-2$^+$ mesodermal cells at this stage denote a subset of mesoderm, important being the lateral plate cardiogenic mesoderm[25]. Administration of soluble BMP-2 to chick embryo explant cultures induces full cardiac differentiation in stage 5 to 7 anterior medial mesoderm, a tissue that is normally not cardiogenic[70].

Since BMP-2 is a cardiogenic factor as well as expressed in the cardiogenic mesoderm, it is highly imperative to investigate the molecular nature and phenotype of the mesodermal cells expressing BMP-2 during the early stages of development in the context of cardiomyogenesis. Also, It has been well documented that BMP-2 is a potent apoptotic inducer and a potent neurotrophic factor depending upon the target cells in a concentration gradient dependant manner, mostly by its paracrine mode of action[71-73]. Thus, BMP-2 plays a pivotal role not only during cardiomyogenesis but also during other early embryonic patterning and lineage specification. Till date, the molecular nature and phenotype of the mesodermal cells expressing BMP-2 during the early stages of development have not yet been characterized leaving a black box in understanding their molecular interactions with the target cells in the vicinity to conclude their role during early embryonic patterning and lineage determination. This is partly due to the pleiotrophic effects of BMP-2 and mainly due to the practical difficulty in isolating pure early stage BMP-2 expressing cells in sufficient quantities during early embryonic development *in vivo*.

Extensive investigation of the *in vitro* ES cells-based developmental model in the last 2 decades has proven it to be an invaluable tool to unravel the molecular enigma during the embryonic development in particular to better understand the mechanisms by which lineage decisions are made during early embryogenesis[12]. Recapitulation of early embryonic development, access to the early embryonic development, fine control over the process of differentiation, relative easiness to harvest the experimental material in sufficient quantity and quality in a very short time and to investigate molecular developmental events applying reporter gene manipulations make *the in vitro* ES-based model superior over the *in vivo* animal models[12,62].

To address the molecular nature and behavior of the BMP-2$^+$ mesodermal cells during their differentiation into their lineage specific somatic cells, we first established an ES cell-derived transgenic Bone morphogenetic protein-2 (BMP-2)-expressing lineage for

developmental studies *in vitro*. In order to identify all the possible signal transduction pathways and biological processes characteristic of the BMP-2$^+$ cells, we performed large-scale expression studies using Affymetrix expression microarrays. Our study on the phenotypic identification of the ES cell-derived BMP-2 lineage specific cells shows that the early BMP-2 population contained a heterogeneous population of predominantly neural crest stem cells and their lineages-smooth muscle cells (SMC), epithelial like cells, astrocytes and melanocytes. When early BMP-2$^+$ population was further cultured under certain conditions contained cardiomyocytes, macrophages and osteoblasts. Interestingly, these are the cell phenotypes which need BMP-2 for their phenotypic induction and demonstrates the presence of a multi-lineage progenitor phenotype resembling neural crest stem cells. More over, identification of the key signal transduction pathways induced or repressed in BMP-2$^+$ cells explains the observed potential of BMP-2 in modulating early embryonic development, in particular the mesodermal patterning.

4.4.1.Generation and analysis of the BMP-2$^+$ ES cell clone

The transgenic BMP-2$^+$ ES cell line was generated with the linearised pBMP-2-Puro IRES2 EGFP construct by stable transfection. The transfected clones are neomycin resistant. The ES cells do not express BMP-2 in the undifferentiated state but express BMP-2 during the course of differentiation at a later stage as shown in the RT-PCR data in figure 34A, when the ES cells were induced to undergo differentiation by the hanging drop protocol. Normally, the BMP-2 transcript expression starts to show up on day 2, gradually increases in expression level until its peak expression on day 5 after which the transcript expression is at the basal level even after 10days of differentiation. The ES cells and EBs from the BMP-2 clone faithfully behaved as the wild type ES cells and EBs (figure 34A and B). During the course of differentiation (by hanging drop protocol), the EGFP fluorescence increases significantly after 2 days and initially the EGFP expressing cells found to be scattered within the 2-days to 4-days old EBs (Figure 34C). As the differentiation continues, the EGFP fluorescence peaks on day 5 and the EGFP expressing cells are localized to a particular region in every EBs as shown in figure 34C.

4.4.2. Isolation and transcriptomic Profiling of BMP-2$^+$ cell population

Isolation and further characterization of the BMP-2$^+$, puromycin-resistant cells have been optimized according to the protocol described in Figure 35A. Briefly, single cell suspension of BMP-2$^+$ ES cells was seeded in bacteriological dishes for two days to form 2-day old EBs. Then, the 2-day old EBs were transferred into gelatine coated tissue culture dishes and cultured for further 2 days. Thereafter, plated EBs were treated with 3µg/ml puromycin for the subsequent 3 days. After trypsinisation of puromycin-resistant 7-day old

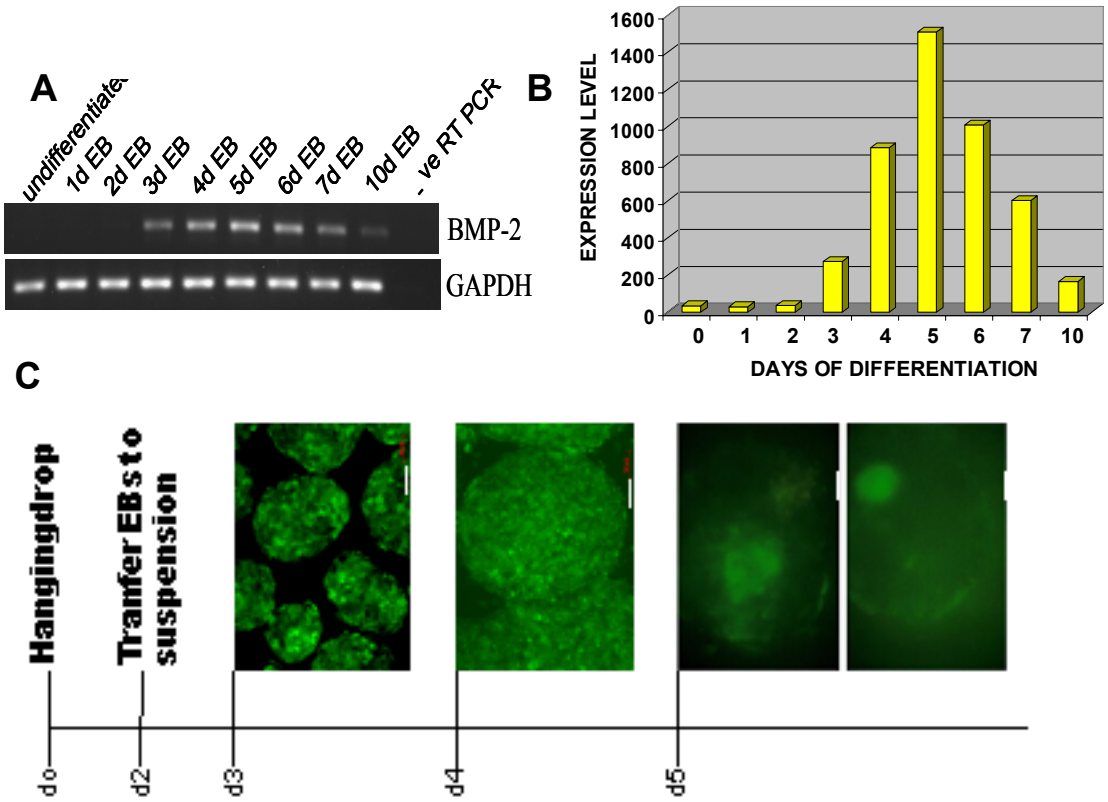

Figure 34 A., Analysis of the BMP-2 transcript expression by RT-PCR from EBs derived from BMP-2 ES clones, B., Differential expression pattern of BMP-2 transcript in differentiating EBs as obtained from the transcriptomic profiling by Affymetrix. C., Expression of the EGFP during differentiation of the BMP-2 ES cells induced by the conventional hanging drop protocol. Scale bar represents 50µm.

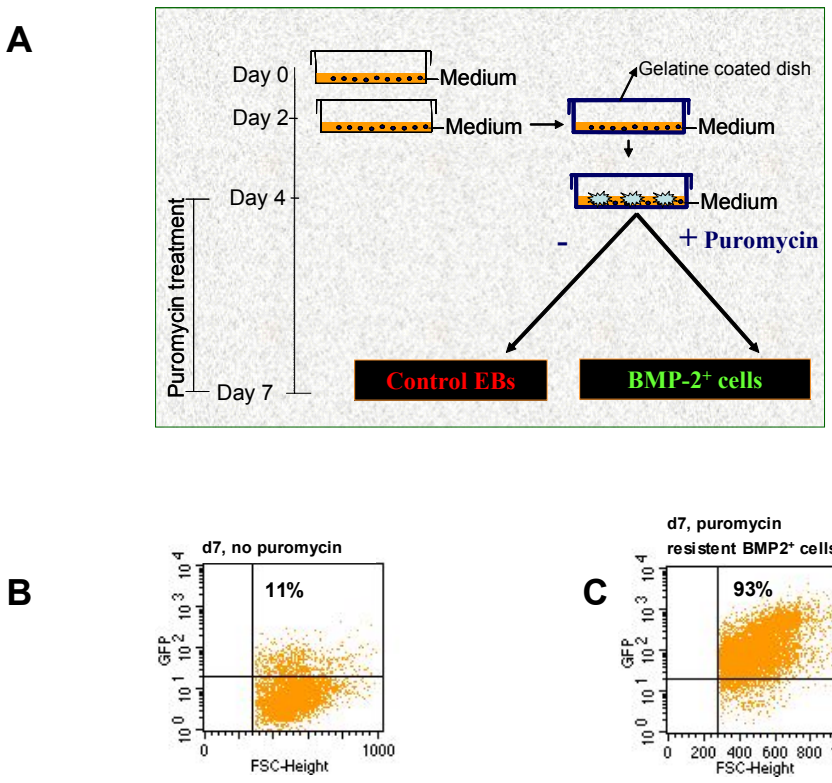

Figure 35 A, Protocol for isolation of puromycin resistant BMP-2$^+$ cells after treating the plated 4-days old EBs with 3µg/ml puromycin for 3 days. **B**, **C**, FACS analysis of the trypsinized untreated control and puromycin resistant BMP-2$^+$ cells.

BMP-2$^+$ cells, FACS analysis has been performed. As demonstrated in Figures 35.B and 35.C, after 3 days of puromycin treatment, EGFP fluorescing and puromycin resistant BMP-2$^+$ cells (hereafter called BMP-2$^+$ cells) accounted for 93% of the cells whereas the control EBs without puromycin treatment (hereafter called control EBs (=7-day old EBs)) contained only 11% of BMP-2$^+$ cells. This resulted in an enrichment of nearly 8.5 fold of the BMP-2$^+$ cells.

As demonstrated in figure 36A, plating of the BMP-2$^+$ cells in gelatine coated tissue culture dishes for the subsequent 3 days in the presence of puromycin results in a bright EGFP-positive BMP-2$^+$ cell population. Furthermore, the BMP-2 protein has been detected by immunostaining using BMP-2-specific antibodies (Figure 36B and 36C). The undifferentiated BMP-2 ES cells were included as negative control (Figure 36D). As demonstrated, BMP-2 is only detected in the cytosol and specifically in vesicles of the BMP-2$^+$ cells. Plating and culture of the BMP-2+ cells in the presence of puromycin for 8 more days resulted in a heterogeneous population/colonies of cells with different morphologies as shown in Figure 37.

4.4.3 Phenotypic charecterisation of BMP-2$^+$ cell lineages

Expression of genes in the BMP-2$^+$ cells associated with plasticity, mesodermal and neural crest stem cell phenotypes

The early BMP-2 lineage cells are still in the state of plasticity

BMP-2$^+$ cells significantly upregulate Oct4 and Nanog transcripts expression compared to the 7-days old control EBs in which several somatic cell types are developed (Figure 38A) but at a level lower than ES cells. This implicates that there are some population of BMP-2$^+$ cells with multi-lineage progenitor phenotypes, which are still in the state of certain plasticity and which can be induced to give rise to different cell fates depending upon the stimuli they receive. This is further confirmed due to the upregulated expression of Leukemia Inhibitory Factor (LIF) in BMP-2$^+$ population compared to the 7-days old control EBs. Interestingly, the transcripts of Activin, Nodal and Cripto are also upregulated in BMP-2$^+$ population compared to the 7-days old control EBs. Recently, it has been demonstrated that TGF-β/Activin/Nodal signaling pathway is necessary for the maintenance of pluripotency in embryonic stem cells[74]. Therefore, the increased level of the pluripotency associated gene markers-Oct4 and Nanog might be partly explained by the increased expression of LIF, Activin and Nodal observed in the BMP-2$^+$ cells (figure. 38).

The BMP-2$^+$ cells exhibit mesodermal characteristics

The expression levels of the mesodermal markers in BMP-2$^+$ cells show increased levels of expression of nodal, activin, eomesodermin, cripto, and Mesp2 whereas the expression of T-bra and Mesp1 was lower in the BMP-2$^+$ cells compared to the control 7-days old EBs (Figure 38). In this context, it has been shown that Activin and Nodal which are members of transforming growth factor beta (TGF-β) superfamily play a pivotal role in inducing and patterning mesoderm and endoderm, and in regulating neurogenesis and left-right axis asymmetry (for review see[75]). Nodal genes have been identified in numerous vertebrate species and are expressed in specific cell types and tissues during embryonic development[75]. Moreover, Nodal null mouse mutants lack mesoderm and overexpression of Nodal in mouse ES cells leads to up-regulation of mesodermal and endodermal cell markers emphasizing the key role of Nodal for mesoderm formation[76]. Also, it is repeatedly shown that Activin is involved in the mesodermal pattering during *Xenopus* embryo development[77]. Cripto is the founder member of the EGF-CFC family initially related to the epidermal growth factor (EGF). Cripto is expressed in tumor tissues and studies in the mouse have established an essential role of cripto in the formation of precardiac mesoderm and differentiation to fucnctional cardiomyocytes[78]

The T-box gene *Eomesodermin (Eomes)* is required for mesoderm formation and the morphogenetic movements of gastrulation. It has been shown in the mouse that lack of *Eomes* abrogates the formation of embryonic and extraembryonic mesoderm[20]. In this context, it has been shown that *Eomes* is specifically required for the directed movement of cells from the epiblast into the streak in response to mesoderm induction[20]. Interestingly, we found a dramatically low level of T-Brachyury expression in BMP-2$^+$ cells compared to the 7-days old control EBs, indicating that the either BMP-2$^+$ cells represent a subset of mesodermal population, the mesoderm formation is nearly complete at the time of BMP-2 expression whereby T-Brachyury expression is downregulated or the necessary signals from the non-BMP-2 population to induce stronger T-brachyury expression are eliminated due to puromycin selection. T-Brachyury is an essential gene for the mesoderm formation as demonstrated in the mouse[65]. Mesp1 and Mesp2 are basic helix-loop-helix (bHLH) transcription factors that are co-expressed in the anterior presomitic mesoderm (PSM) just prior to somite formation[79] in the mouse embryo. Furthermore, it has been shown that Mesp1 has a significant role in the epithelialization of somitic mesoderm and it has been assumed that Mesp2 is responsible for the rostro-caudal patterning process itself in the anterior PSM[79]. Recently, it has been shown that Mesp1 is expressed in almost all of the precursors of the cardiovascular system in the mouse, including the endothelium, endocardium, myocardium, and epicardium[80]. Thus, the in vitro derived BMP-2 lineage cells exhibit more mesodermal characteristics. This conclusion is further supported by the

derivation of most of the mesodermal tissues and complete absence of endodermal phenotypes from these BMP-2 cells in the later stages as described below.

BMP-2$^+$ cells lack endodermal phenotypes

Interestingly, transcripts of α-feto protein (AFP) and Sonic Hedgehog (Shh) were not detectable in BMP-2$^+$ cells (figure 38A). AFP represents a marker for the endoderm-derived hepatocytes. The expression pattern of Sonic Hedgehog studied in several species indicates that Shh is essential for the endoderm-derived organ development such as foregut development, gut development, gastrointestinal duodenal and pancreas deveolpment[81]. These results show a dramatically reduced or more likely the complete absence of the endodermal lineage specific cells.

The BMP-2$^+$ cell lineage contains neural crest stem cells and their derivatives

The BMP-2$^+$cells contained enriched expression of ectodermal markers-Neurofilament H (NF-H,) and M (NF-M). But it is evident that the BMP-2 cells shared more mesodermal characteristics as described in the previous sections. Further investigation of this contrary situation led to the conclusion that these may be more likely due to neural crest stem cells, as reported in several observations where these cells share a more ectodermal and a less mesodermal characteristics[82-85]. Expression of the neural crest stem cells (NCSCs) specific p75NTR[86] and Nestin transcripts at higher levels compared to the 7-days old control EBs (Figure 39A) confirmed the presence of enriched NCSCs in BMP-2$^+$ cells. In addition, expression of smooth muscle α actin (SMA), astrocytes specific Glial fibrillary acidic protein (GFAP) and melanocytes specific Tyrosine phosphates 1 (Tyrp1) in BMP-2$^+$ cells as shown in figure 39A confirmed the presence of NCSC lineages as well in the BMP-2$^+$ lineage. Expression of p75NTR in BMP-2$^+$ cells was further confirmed by immunohistochemical staining with an antibody against p75^{NTR} on BMP-2$^+$ cells, one day after plating in the absence of puromycin. In addition, presence of glial cells has been confirmed by immunohistochemical staining with an antibody against Glial fibrillary acidic protein (GFAP), on BMP-2$^+$ cells, one day after plating in the absence of puromycin (Figure 39C.b). Notably, it has been reported that the differentiation of NCSCs into their lineage fates is mainly dependant on the presence of BMP-2 in the required threshold level and also the availability of the other factors in combination[83]. In this context, it is well demonstrated that exogenous addition of recombinant BMP-2 to cultured NCSCs isolated from chicken explants of cranial and trunk dorsal neural folds from stage 8/9 embryos resulted in the differentiation of NCSC into glial, melanocytes and smooth muscle cells[83]. It is surprising to note that the BMP-2 local concentration increased by BMP-2+cells

themselves are able to induce the differentiation of NCSCs into their lineages without the exogenous the addition of BMP-2.

During vertebrate embryonic development, as the notochord induces the transformation of surface ectoderm to neuroectoderm, a multipotential middle cell layer develops with characteristics of both cell types. These cells called, the neural crest cells migrate dorsolaterlally to form the neural crest, a flattened irregular mass between the surface ectoderm and neuroectoderm. This layer of cells separates into right and left portions and then migrate to various locations within the embryo to give rise to most structures of the peripheral nervous system (PNS) such as Schwann and glia cells of the autonomic and enteric nervous systems, endocrine cells such as the adrenal medulla and C-cells of the thyroid) as well as non-neural tissues such as pigmented pigment cells of the skin and internal organs, smooth muscle musculature of the cardiac outflow tract and great vessels, pericytes, craniofacial bones, cartilage and connective tissues[87,88]. Wnt1 and c-kit are well known mediators for melanocytes differentiation of NSCS[89,90]and are found to be expressed in the BMP-2$^+$ population. The tyrosine kinase, c-kit, has been found in the cell membranes of hematopoietic stem cells, primordial germ cells and presumptive subepidermal melanocytes[91] Intriguingly, wnt-1 and BMP-2 act synergistically to suppress

differentiation and to maintain NCSC marker expression and multipotency by combinatorial Wnt1/BMP-2 signalling[92]

The presence of Wnt1 transcripts present in BMP-2$^+$ population may be interpreted in 2 ways. 1) The Wnt1 may be involved in the maintenance of neural crest stem cells in their pluripotency state in combination with BMP-2. 2) Wnt1 may be involved in driving the differentiation of NCSCs into melanocytes. Both possible roles by wnt1 cannot be ruled out in BMP-2 population since there are proliferating NCSC on one side (as evident from increase in cell number when subjected to immunohistochemistry), and the occurrence of melanocytes in the same culture on the other hand. The local BMP-2 and/or Wnt1 gradient may drive the neural crest stem cells to produce either smooth muscle cells, pericytes or to melanocytes or to remaining their pluripotent state, respectively.

This is the first study that enables getting ES cells-derived neural crest stem cells and their derivatives all at the same time selectively via BMP-2 promoter based lineage selection approach. The co-expression of Wnt1 and BMP-2 in the same culture indicates the existence of both an environment to keep the neural crest stem cells in stemness and also the stage of ongoing differentiation of NSCS to form melanocytes. Thus, the study on these BMP-2 expressing cells during early differentiation of ES cells will pave the way for the better understanding of the neural crest stem cells and their differentiation into their lineages. The BMP-2$^+$ cells-derived from the ES cells may serve as an ideal model for the neural crest stem biology in the future since the neural crest stem cells and their derivatives can be selectively enriched by the BMP-2 promoter driven lineage selection approach. In addition, it provides a valuable system where the enriched neural crest stem cells prime themselves to differentiate into their cell specific lineages, since the enriched NSCS secrete BMP-2 and causes a BMP-2 gradient negating the supply of exogenous BMP-2 addition. Noggin, an inhibitor of BMP-2 can be used to keep the neural crest stem cells in their plasticity. Once the fine-tuning of BMP-2 derived neural crest stem cells to keep in their plasticity is made, then they will be the potential candidates for the cell replacement therapy, since they can mould into any tissue depending upon the local environment prevailing within the tissue in which they are injected.

BMP-2 cell contain predominantly smooth muscle cells

Figure 40A shows that culturing of the BMP-2$^+$ cells for 8 days in the presence of puromycin resulted in the development of a heterogeneous cell population of cells with different morphologies. Figure 37B indicates cells with smooth muscle-like morphology. The immunohistochemical staining of smooth muscle cells has been performed with an

antibody against smooth muscle α actin, 1 day after plating the BMP-2+ cells (7+1 days in total), 8 days after plating with puromycin (7+8 days in total), 18 days after plating with puromycin (7+18 days in total) and 18 days after plating without puromycin (7+18 days in total) (Figure 40Ca-d). Detection of Smooth muscle cells even 18 days after puromycin treatment indicates that SMC express BMP-2 and therefore they survive the puromycin treatment [93].

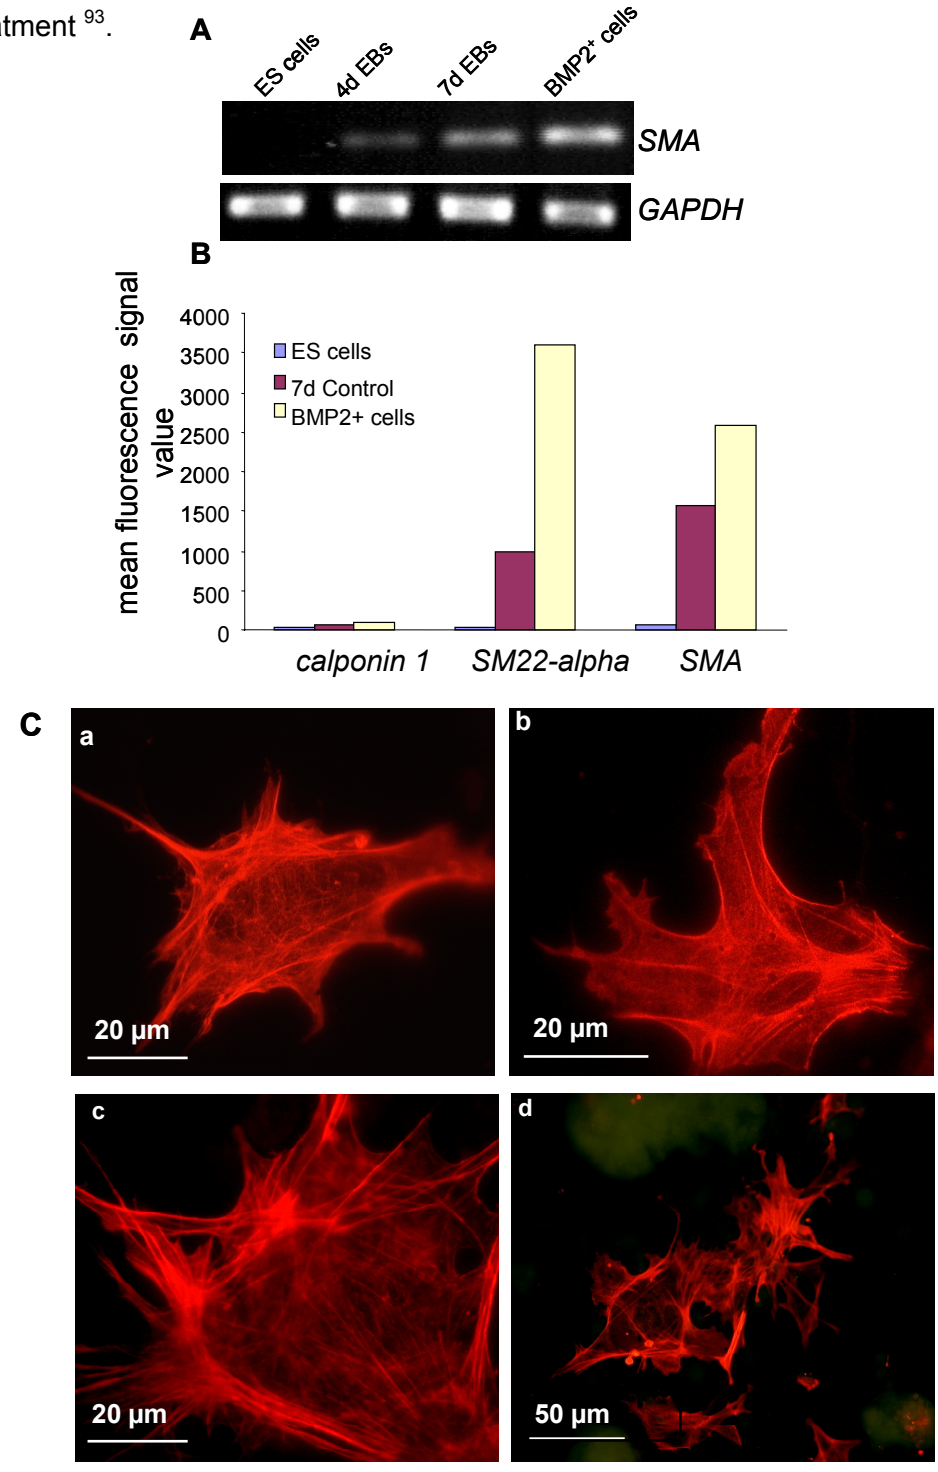

Figure 40. Detection of smooth muscle cells after differentiation of the BMP-2$^+$ cells. A, Expression of SMA in the BMP-2$^+$ detected by semi-quantitative RT-PCR method. B, Diagram indicates the microarray expression levels of various smooth muscle specific genes in BMP-2$^+$ cells. **C(a-d),** detection of smooth muscle cells, 1 day after plating the BMP-2+ cells (7+1 days in total) **(Ca)**, 8 days after plating with puromycin (7+8 days in

total) **(Cb)**, 18 days after plating with puromycin (7+18 days in total) (**Cc**) and 18 days after plating without puromycin (7+18 days in total) **(Cd)**.

BMP-2$^+$ cells give rise to cardiomyocytes after downregulation

The expression level of the cardiac marker genes NKx2.5 (early), MLC-2a, α-cardiac actin and Mef2c is reduced in the BMP-2$^+$ cells compared to the control 7-days old EBs (Figure 41A) suggesting that cardiomyogenesis is repressed in the BMP-2$^+$ cells. Accordingly, also Mesp1 was found to be repressed (Figure 38A). Culturing of the BMP-2$^+$ cells even for further 28 days (35 days in total) in the presence or absence of puromycin did not result in cardiac cell beating clusters (data not shown).

Preparation of hanging drops EBs applying the differentiation protocol (Figure 41B) as previously described[94] from a mixture of BMP-2$^+$ cells with wild type ES cells in a ratio 1:1, 1:2, 1:4, 10:1, 50:1, 1:10 and 1:50, respectively, did not augment/delay the onset of contractile activity in comparison to the control observed on day 12. Also, there were not any significant differences in terms of magnitude of the intensity of the contractility (data not shown). This corresponds to the observation where recombinant BMP-2 added during the differentiation of ES cells, no enhancement of cardiomyogenesis has been observed[95]. In order to investigate the capacity of the BMP-2$^+$ cells to differentiate in cardiac beating cells, secondary EBs were made from these BMP-2$^+$ cells by hanging drop protocol and the differentiation process was observed in comparison to the control EBs. The secondary EBs when made from the BMP-2$^+$ population were contracting on 11th day like the secondary control EBs made from the CGR8 wild type EBs without puromycin and secondary EBs made from the β–actin CGR8 clone transfected with β-actin promoter driven puromycin resistance and EGFP expression cassettes treated in the same way as the secondary BMP-2$^+$ EBs with puromycin. Notably, the intensity of the contracting areas in the BMP-2$^+$ EBs was significantly stronger, compared to the both controls. The whole EB was contracting in a jellyfish like fashion where as in the controls (Fig. 41C). The contracting areas persisted for a longer time when compared to the controls for more than a week. In order to demonstrate that an increased beating activity of the cardiomyocytes generated from the BMP-2$^+$-cells correlates with an increased expression of cardiomyocyte gene markers, we investigated the expression of α-cardiac actin and αMHC in EBs at day 11 secondary EBs. As clearly indicated, an increased expressed level of both cardiac specific genes was observed in the EBs generated from BMP-2$^+$ cells (Figure 41D) compared to both the control secondary EBs.

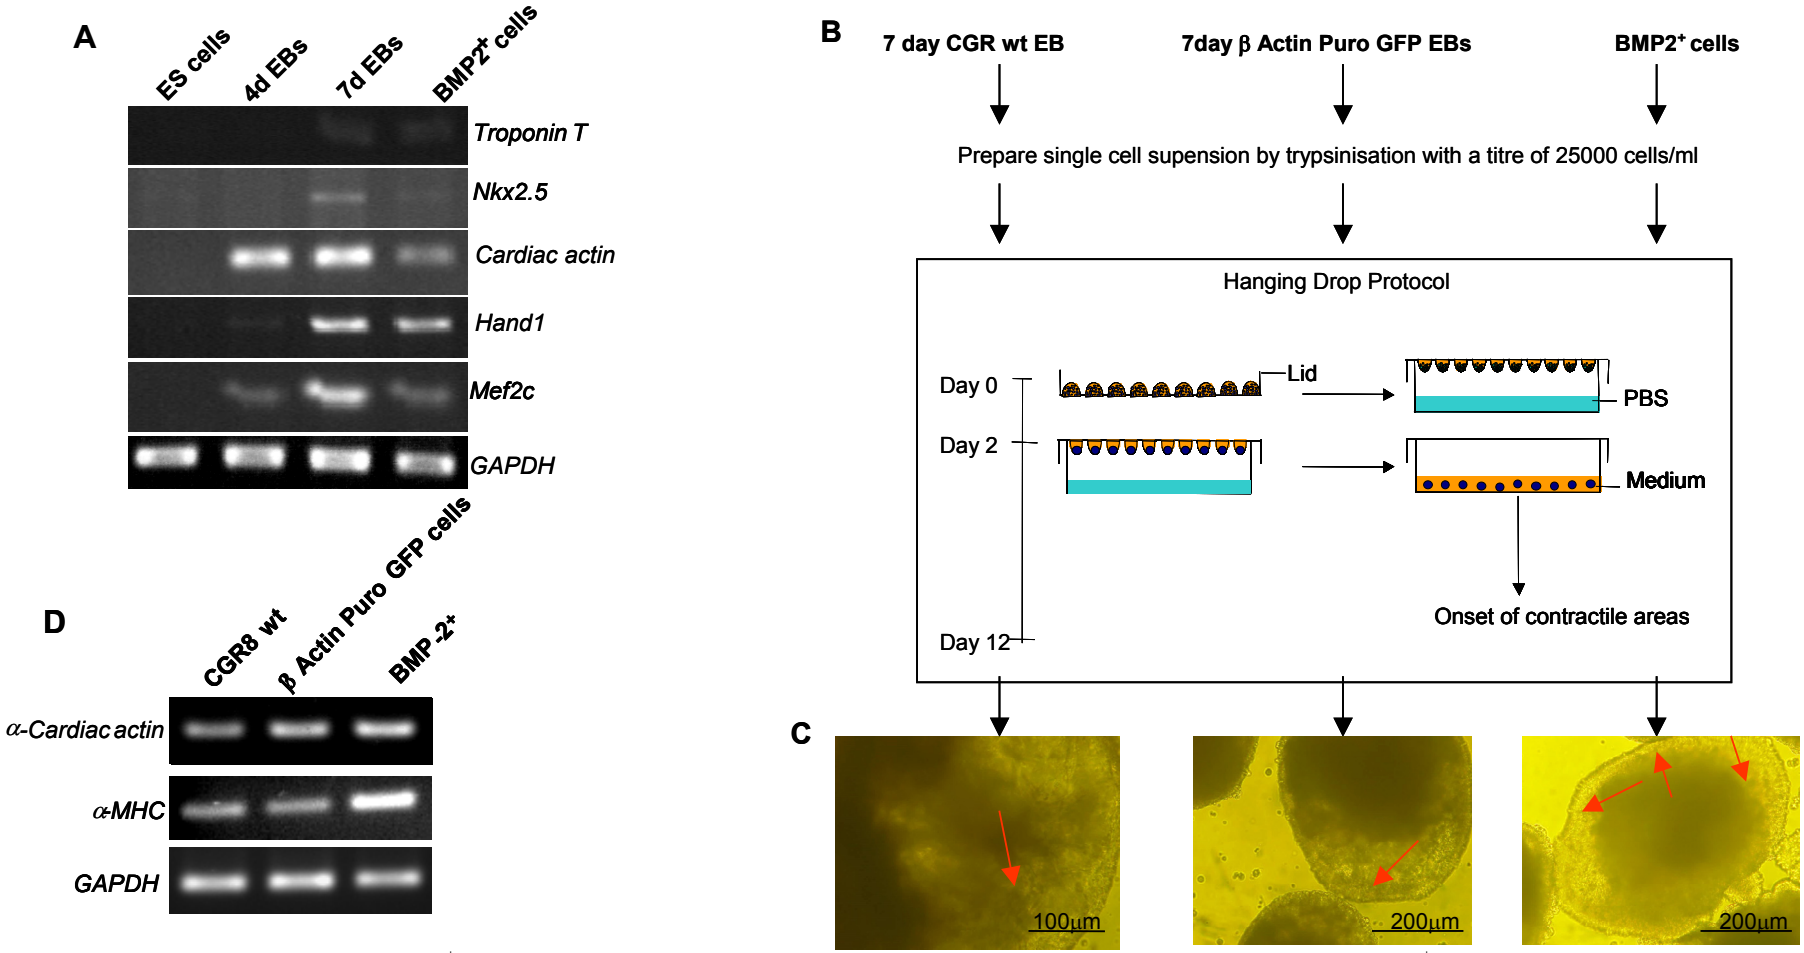

Figure 41. Differentiation of the BMP2$^+$ cells to cardiac cells. **A**, RT-PCR analysis of the cardiac markers in BMP2$^+$ cells and other controls. **B**. Schematic outline of the protocol used to derive cardiomyocytes from BMP2$^+$ cells. **C**, the morphology of the contracting EBs. The red arrows indicate the contracile area(s) in that EB and **D**, RT-PCR analysis of the representative cardiac markers in 12 day secondary EBs derived by hanging drop protocol from single cell suspension obtained from 7 day old primary EBs generated by the hanging drop protocol from CGR8 wild type EBs without puromycin treatment, β-actin puro EGFP EBs and BMP2 EBs with puromycin treatment.

Thus, BMP-2$^+$ cells have the capacity to develop into cardiomyocytes. Interestingly, the cardiomyogenic potential apparently seems to be regulated by the BMP-2$^+$ lineage cells only. These findings suggest that the BMP-2$^+$ cells are primed to become cardiomyocytes independently of the other BMP-2$^+$ negative lineage cells. But the secondary EBs maintained with puromycin and the contractile secondary EBs when treated with puromycin did not contain cardiomyocytes. So, it is imperative to note that the cardiomyocytes don't express BMP-2 but descend from the BMP-2$^+$ mesodermal cells. At the same time, the cardiomyocytes developed from the BMP-2$^+$ cells are dependant on paracrine action of BMP-2 secreted by the neighboring cells of BMP-2 lineage cells[96].

Vascular and haematopoietic cell gene markers from BMP-2 population

Expression of E-cadherin, Flk1, Flt1, Pecam1 and Runx1 shows the presence of vascular endothelial progenitors in the BMP-2$^+$ population (Figure 42A). As demonstrated in figure 42B, BMP-2$^+$ cells are able to differentiate into cells with an epithelial/endothelial morphology after culturing for 8 days in the presence of puromycin. Detection of epithelial-like cells has been confirmed by immunohistochemistry. As indicated in figure 42Ca-d epithelial-like cells were detected even after 11 days after culturing in the presence of puromycin.

Expression of c-kit and CD34 and Runx1 indicates the presence of hematopoietic stem cells in BMP-2 population (Figure 42A). *Ihh* that is implicated in haematopoiesis and vasculogenesis[97] also is expressed in the BMP-2$^+$ cells but the expression level is lower than that of the control cells. Flt-1 also known as vascular endothelial growth factor receptor 1 (VEGFR-1) is a high-affinity tyrosine kinase receptor for VEGF and is normally expressed only in vascular endothelial cells. However, Flt-1 transcript was recently found to be expressed in human peripheral blood monocytes[98]. Monocytes are known to differentiate into a variety of cell types such as osteoclasts in bone, Kupffer cells in liver, dendritic cells in the immune system, and mature macrophages in a number of tissues[98] . Expression of Flt-1 and c-fms in BMP-2 population indicates the possible monocyte-macrophage lineage existence in the BMP-2$^+$ cell population.

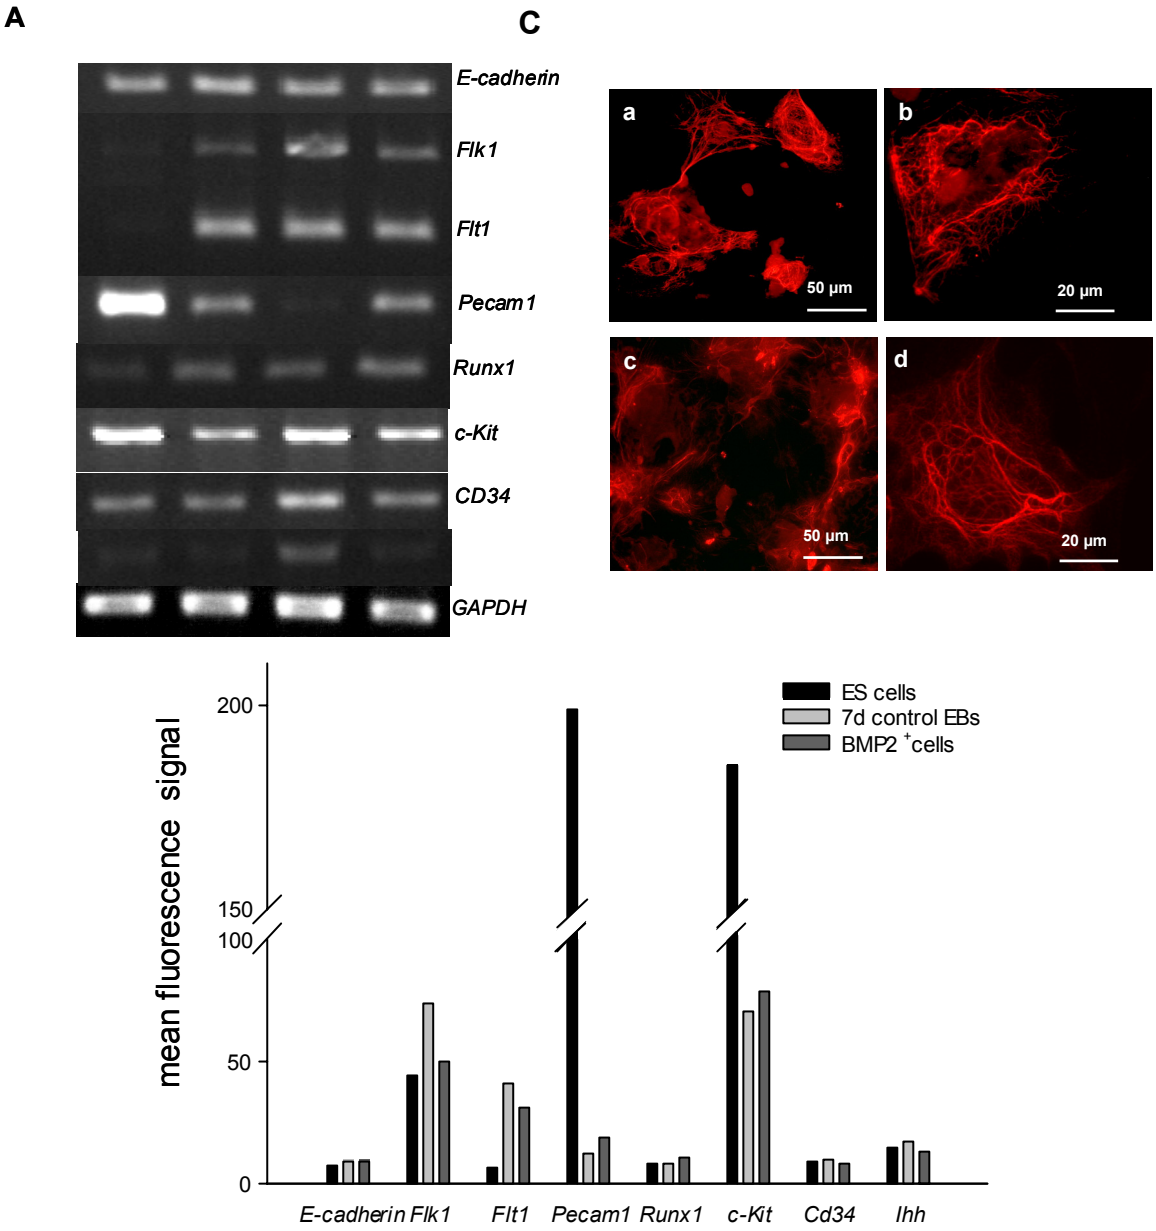

Figure 42 **A**nalysis of the vascular and haematopoietic cell gene markers in BMP-2^{+} cell population**. A**, RT-PCR analysis of the BMP-2^{+} cells. **B**, Relative fluorescence signal units as obtained from Affymetrix profiling for the genes presented in A. **C**, Immunuostainings with anti-pan cytokeratin over the period of time to show the presence of epithelial like cells. **Ca**, one day after plating the BMP-2+ cells (7+1 days in total). **Cb**, 8 days after plating with puromycin (7+8 days in total). **Cc**, 18 days after plating with puromycin (7+18 days in total). **Cd**, 11 days after plating without puromycin (7+11 days in total).

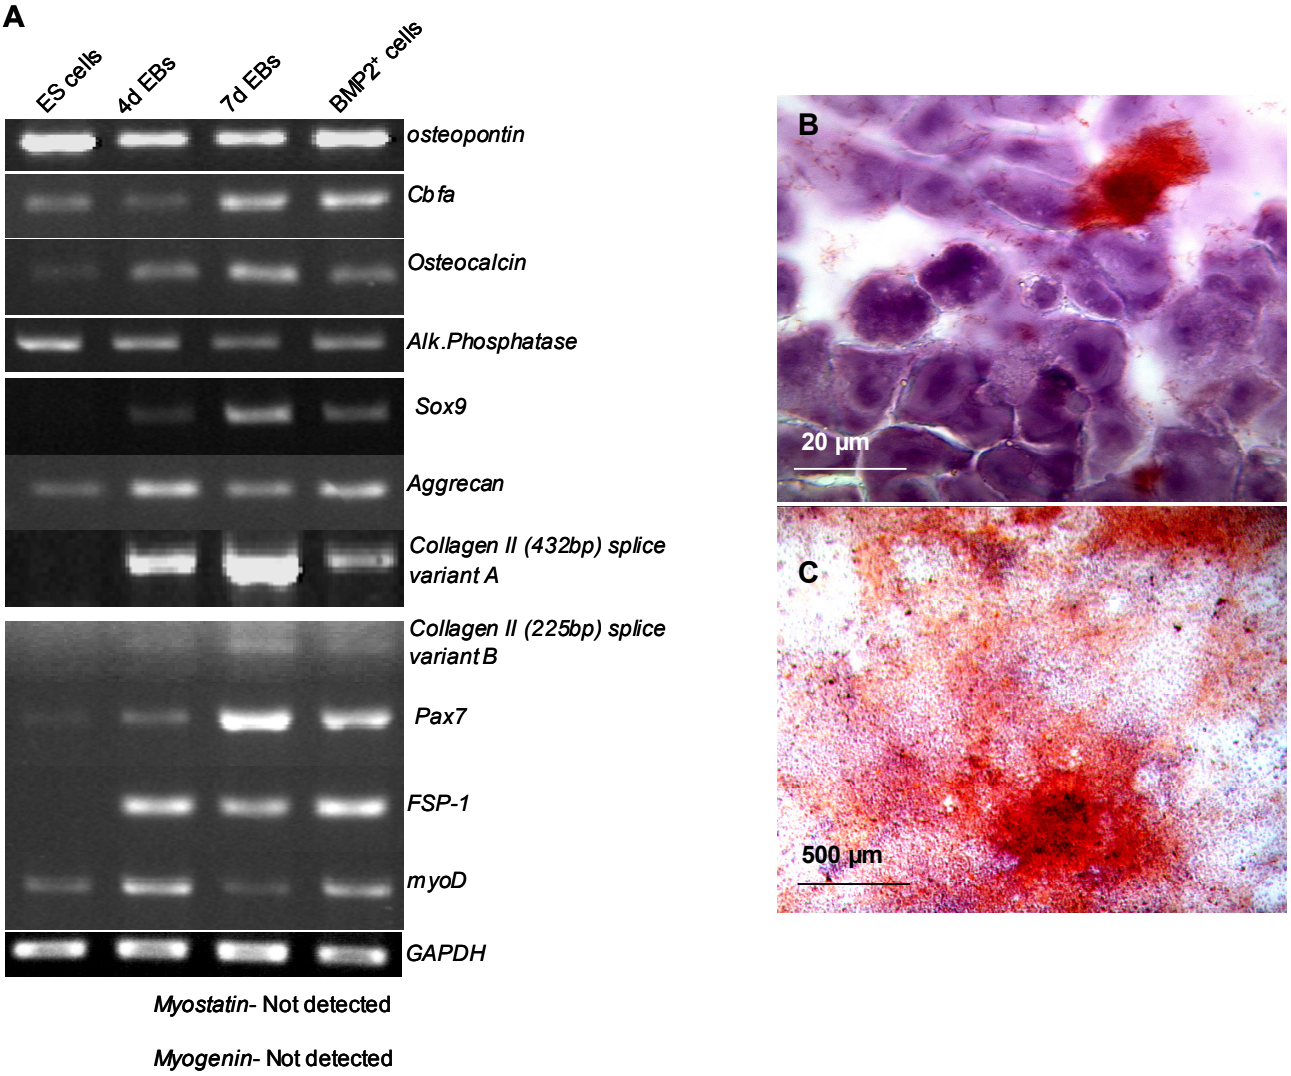
BMP-2$^+$ cells give rise to osteoblasts and express gene markers for satellite cells and fibroblasts

Expression of osteopontin, Cbfa, osteocalcin and alkaline phosphatase in BMP-2$^+$ cells showed the possible occurrence of osteoblasts (Figure 43A). When BMP-2$^+$ cells plated and maintained with the differentiation medium and puromycin showed Alizarin red positive clusters after 18days (Figure 43B) indicating the first appearance of osteoblasts. After 35 days of culturing in the presence of puromycin, brightly stained with Alizarin red were observed confirming the occurrence of osteoblasts in culture (Figure 43C). These results show that the puromycin resistant BMP-2$^+$ cells per se are cable of differentiating into osteoblasts. It may be also possible that the osteoblasts might be developed from the BMP-2$^+$ derived NCSC cells in the presence of an increased BMP-2 concentration for longer periods of time[99].

Expression of the transcription factor Sox9, the proteoglycan aggrecan, collagen II (with 2 alternate splicing forms) was detected in the BMP-2$^+$ population indicating the existence of chondrocytes[100](Figure 43A) . Sox9 is a key transcriptional factor for chondrocytic differentiation of mesenchymal cells via chondrocytes-specific enhancer of the pro alpha1 (II) collagen[101]. Expression of Pax-7 and myoD shows the presence of satellite cells[102,103]. Satellite cells represent a distinct lineage of myogenic progenitors responsible for maintenance of skeletal muscle[104]. MyoD is only expressed when satellite cells are activated to proliferate and differentiate into primary myoblasts, which will in turn differentiate into cells of the myofibres of skeletal muscles[103]. An elevated level of MyoD in the BMP-2$^+$ population indicates either the proliferation or the differentiation of satellite cells into primary myoblasts in BMP-2 culture. But the expression of myogenin and myostatin was not detected in the BMP-2$^+$ cell population suggesting the absence of skeletal muscle cells by RT-PCR even after 40 cycles. Interestingly, it has been reported that the satellite cells can spontaneously differentiate into adipocytes in an alternative mesenchymal pathway[105]. Expression of FSP-1 shows fibroblast phenotype occurring in the BMP-2$^+$ cell population. FSP-1 has been implicated in the epithelial-mesenchymal transition and is a representative marker for mesenchymal cells[106] .



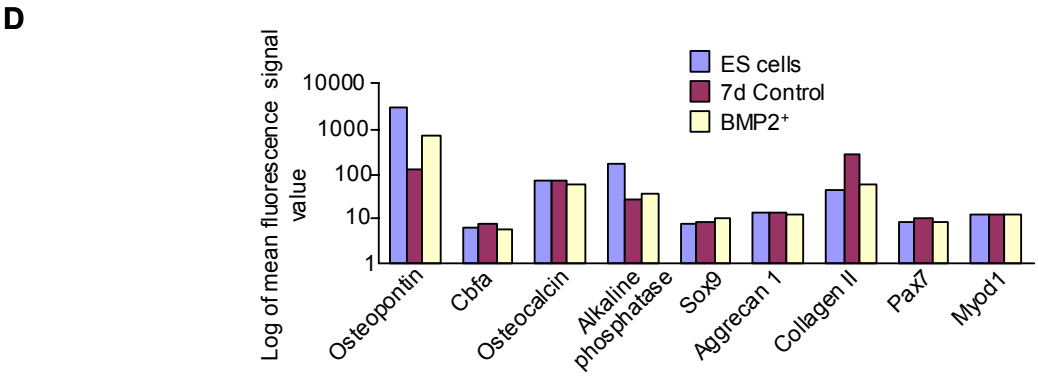


Figure 43. analysis of osteoblast, chondrocyte and myocyte specific markers in BMP-2^{+} cells. **A**, RT-PCR analysis in BMP-2^{+} cells. **B, C**, Alizarin stanings on 18th day after plating the BMP-2+ cells (7+18 days in total) and on 28 days after plating (7+28, 35 days in total). **D**, Relative fluorescence signal units as obtained from Affymetrix profiling for the genes presented in A.

BMP-2 cell lineage contains monocytes but not mature adipocytes

The RT-PCR analysis of the BMP-2$^+$ population showed the expression of the pre-adipocyte gene marker pref-1[107], the pan-adipocyte markers PPARγ[108] aP2, Glut4[109] and LPL as well as the pan- macrophage marker c-fms[107,108,110](Figure 44A and D). Although, the markers PPARγ, aP2 and Glut4 are unique to adipocytes, expression of these genes is also found to be expressed in macrophages. Similarly, trophoblast lineage also expresses c-fms[107]. Notably, the cells-derived from the BMP-2$^+$ cell population after 11 days of cultivation in the presence of puromycin were not found to be positive for either Oil Red O or anti F4/80 stainings eliminating the occurrence of mature adipocytes and macrophages in the later stages (data not shown). Also, no expression of adipsin[111], a marker for mature adipocytes, could be detected demonstrating the absence of the mature adipocytes in the BMP-2$^+$ cells. Thus, the BMP-2$^+$ cell population contains only the pre-adipocytes expressing PPARγ, aP2, Glut4 and Pref-1 but not adipsin. Apparently, other factors secreted by BMP-2 negative cells are required for maturation of preadipocytes to adipocytes.

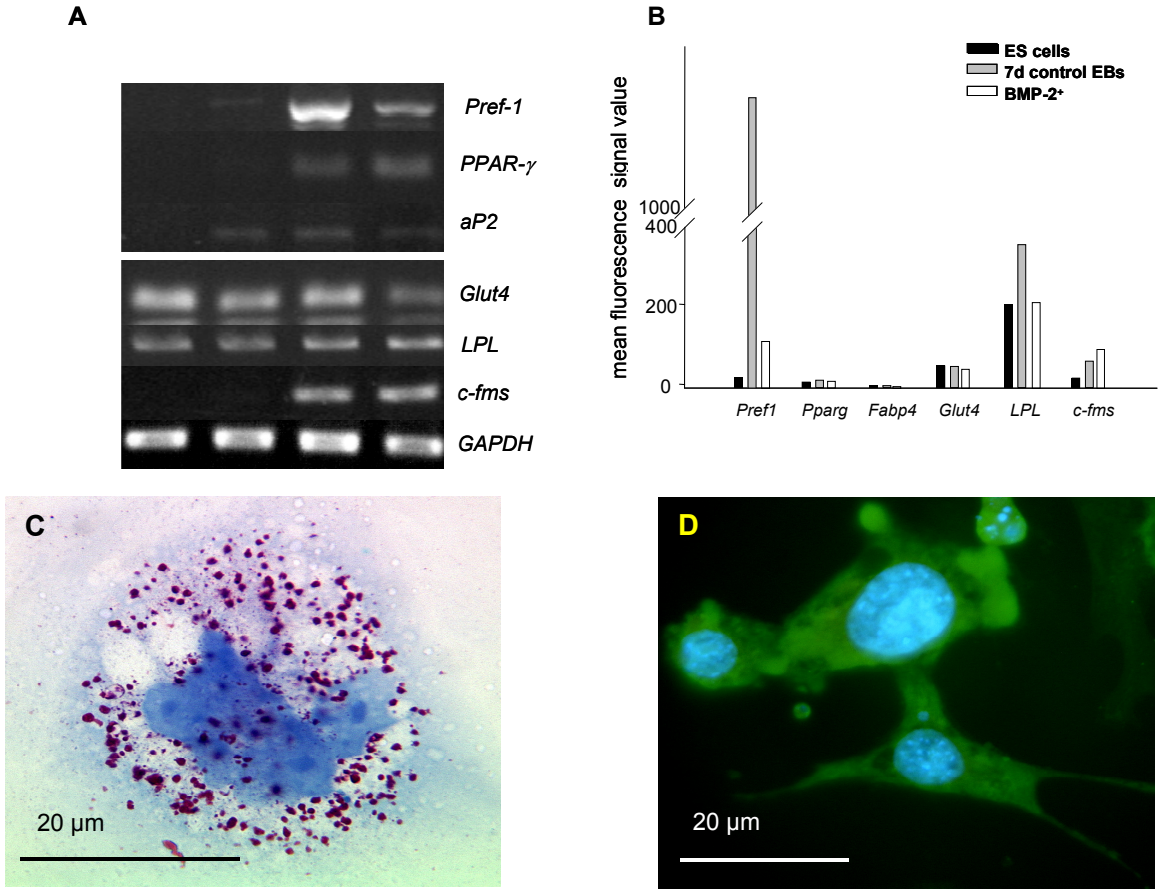

Figure 44. **A**, RT-PCR analysis of adipocyte specific markers. **B**, Relative fluorescence signal units as obtained from Affymetrix profiling for the genes presented in A. **C**, Sudan red staining on 11 days old puromycin untreated culture after plating the BMP-2$^+$ cells (7+11, 18 days in total). **D**, F4/80 Immunuostaining on 18 days old puromycin untreated culture after plating BMP-2$^+$ cells (7+18, 25 days in total).

Notably, after 11-days of BMP-2$^+$ cells culturing in the absence of puromycin, there were cells stained with Sudan Red and F4/80, a marker for macrophages as shown in figure 43B and 43C. These findings suggest that macrophages are derived from differentiated BMP-2$^+$ cells in which BMP-2 expression is downregulated at a later time.

4.4.4 Selective enrichment of different BMP-2$^+$cell phenotypes with puromycin

When the different day EBs were treated with puromycin for 3 days and when the subsequent puromycin treatment was either discontinued, or maintained all the time or maintained in 3 days alternating intervals as shown schematically in figure 45A, different BMP-2 lineages are enriched depending on the starting day of puromycin treatment and the subsequent puromycin selections. Cardiomyocytes were enriched when the 6day EBs were treated with puromycin for 3 days and discontinued the treatment after that. On 19th, when analyzed with semi-quantitative PCR, the cardiomyocytes are enriched when compared to the other BMP-2 lineage phenotypes. When the wild type CGR8 EBs were treated in the same manner, there were no viable cells even after 19 days, implying that the 3 days of puromycin at 3μg/ml concentration is very effective in selecting BMP-2 lineage cells with highest purity. The enrichment of the particular BMP-2 lineage at the respective conditions is color coded with a blue box in figure 46. It is worthwhile to note that in the all the conditions, the enrichment of a particular lineage was found but in addition to other phenotypes. This approach did not select only one phenotype at the whole expense of the others.

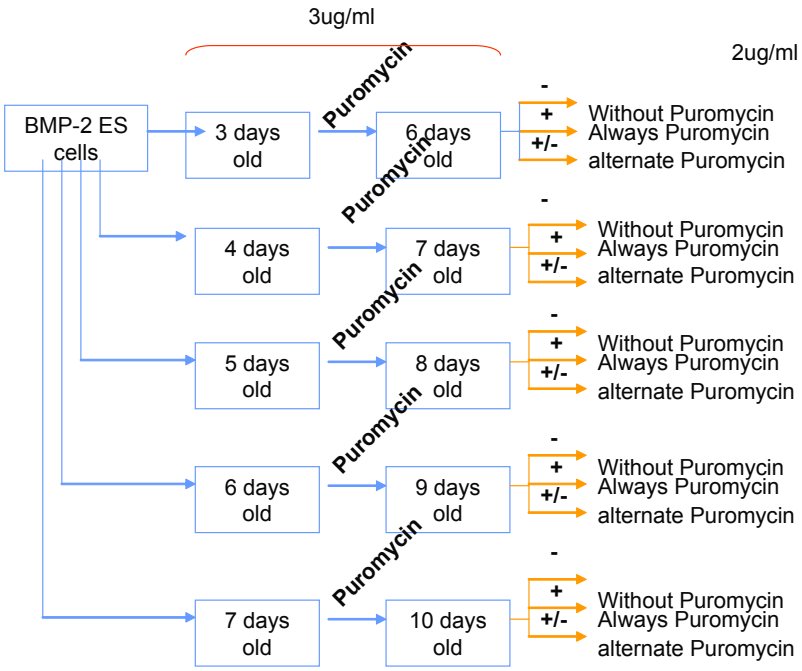

Figure 45. Schematic overview of puromycin treatment on different stage EBs and subsequent puromycin treatment conditions. All the time the first puromycin treatment was 3ug/ml for 3 days and later either the puromycin at a concentration of 2ug/ml was added to the culture or discontinued completely or added in regular 3 days intervals. Finally on day 19, the RNA was isolated from every sample and analyzed for the enrichment of the BMP-2 lineage cells.

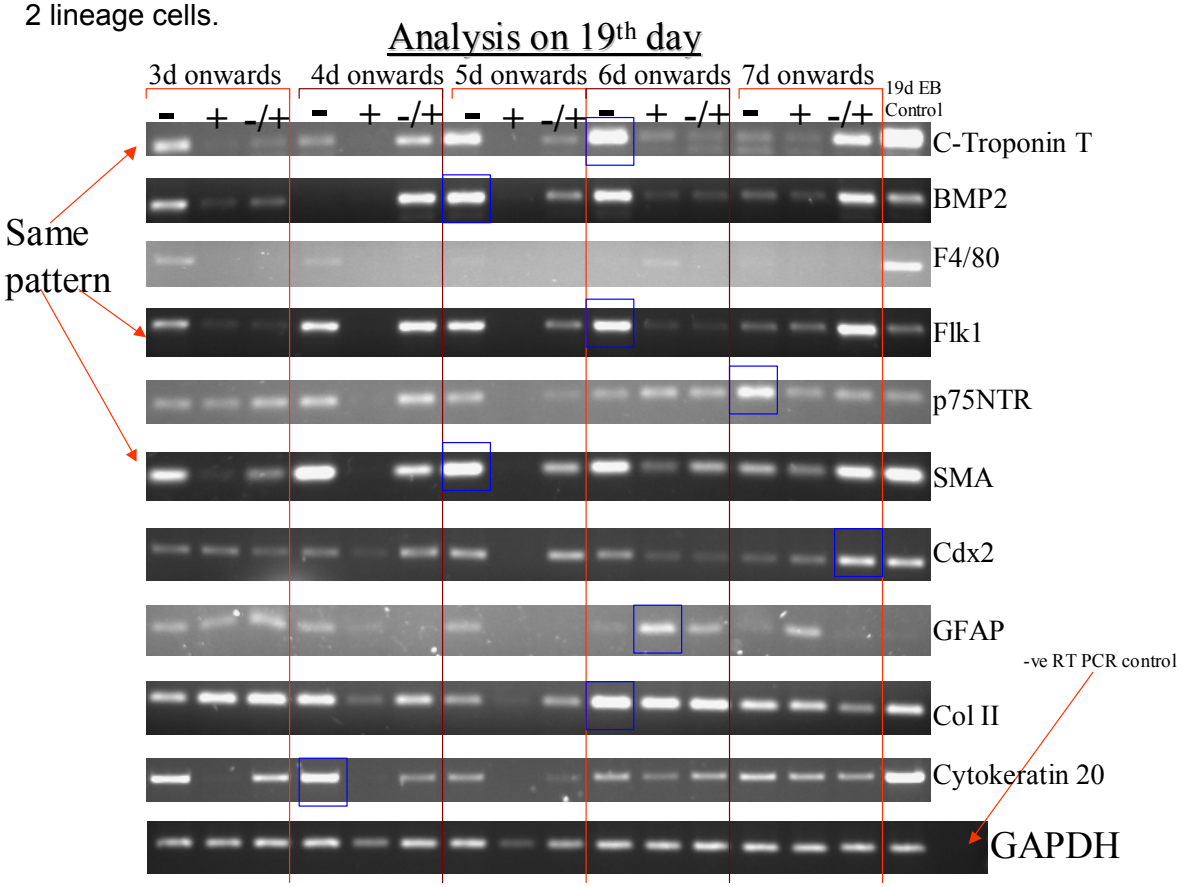

Figure 46. RT-PCR analysis of the BMP-2 mesodermal lineage marker genes on 19th day after the different day EBs were treated with puromycin for 3 days and then either discontinued or continued all the time or in alternative intervals of 3 days.

4.4.5 Validation of Affymetrix data by quantitative real time PCR

The affymetrix data obtained from the ES cells from the BMP-2 clone, puromycin treated 7day EBs (BMP-2+ population and puromycin untreated 7 day EBs) were verified by quantitative real time PCR analysis of the pluripotent and germ layer specific genes – Nanog, T- Brachyury, Bmp-2, Neurofilament H, Sox 17 and a- myosin heavy chain. As seen in the figure 47, the Real time PCR data correlated very well with the affymetrix data.

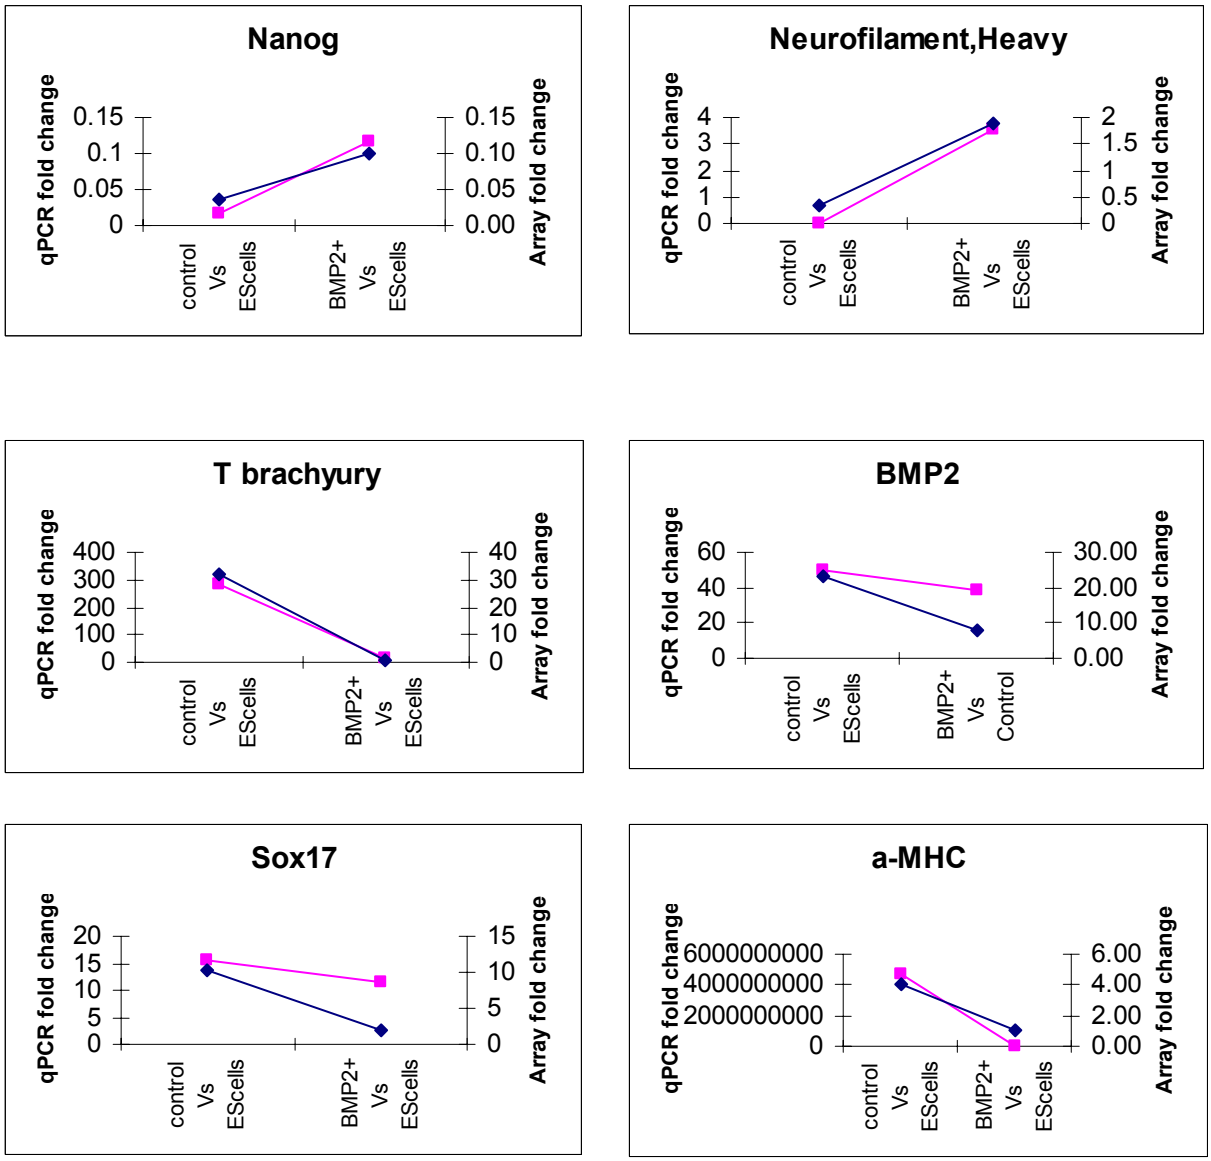

Figure 47. Validation of the Affymetrix data by Quantitative real-time PCR analysis of 5 representative genes. The fold change was calculated by using the formula, fold-change = $2^{-(\Delta C_t \text{ gene1} - \Delta C_t \text{ gene2})}$. ΔC_t of the gene in the sample in which it is expressed lowest is taken as ΔCt gene2 to calculate the fold change using the above formula. The pink line represent results from quantitative PCR and the blue line from affymetrix data.

4.4.6 Transcriptomic analysis of the BMP-2$^+$ cell population

To rule out the differentially expressed transcripts are specific to BMP-2$^+$ cell and are not due to the puromycin application, transgenic β actin clones were generated in the same way like the BMP-2 clones except that the β actin promoter instead of the BMP-2 promoter was used to serve as puromycin treatment controls. Under the same experimental conditions as for the derivation of BMP-2$^+$ cells, on day 4 the EBs were either treated with puromycin or untreated for the subsequent 3 days. On day 7, the RNA samples were prepared from the βactin ES cells, 7 day old puromycin treated β-actin EBs and untreated control β-actin EBs. The samples were affymetrix profiled in the same way as for the BMP-2 samples.

As the first step, the differentially expressed genes due to puromycin application were analyzed. There were 6 unique transcripts with student t-test value of $p<0.01$ differentially expressed between puromycin treated 7day β actin EBs and untreated β-actin EBs and were excluded from the BMP-2 transcriptome analysis.

4.4.6 Major pathways / biological processes differentially regulated in BMP-2$^+$ cells

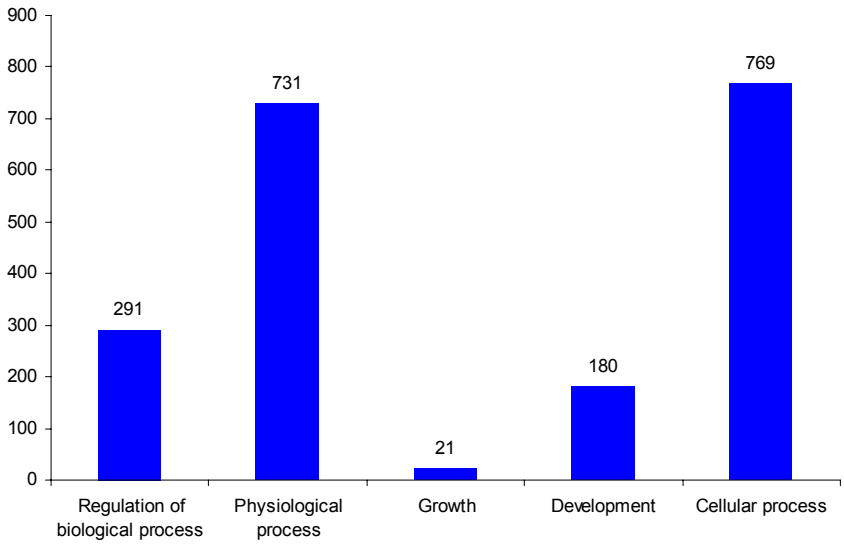

Figure 48. An overview of the number of transcripts differentially expressed in BMP-2$^+$ population according to different Gene Ontologies (GOs), as analyzed with DAVID functional annotation tool.

Overall, there are 1682 unique transcripts differentially expressed (2 fold up or 2 fold down with an ANOVA p value cut off of less than 0.01) compared to either the BMP-2 ES cells or 7day old control EBs. Among them, 28 transcripts participate in MAPK

signaling pathway, 19 transcripts in Wnt Signaling and 13 transcripts in TGFβ signaling pathways. 19 transcripts take part in cell cycle. This shows that the BMP-2 population also has several dynamically ongoing functional signaling cascades, which are implicated to play a crucial role in early embryonic patterning. Overall, among the 1682 transcripts differentially expressed in BMP-2$^+$ cells in comparison to BMP-2 ES cells and 7 day control EBs, 206 genes are implicated in embryonic development.

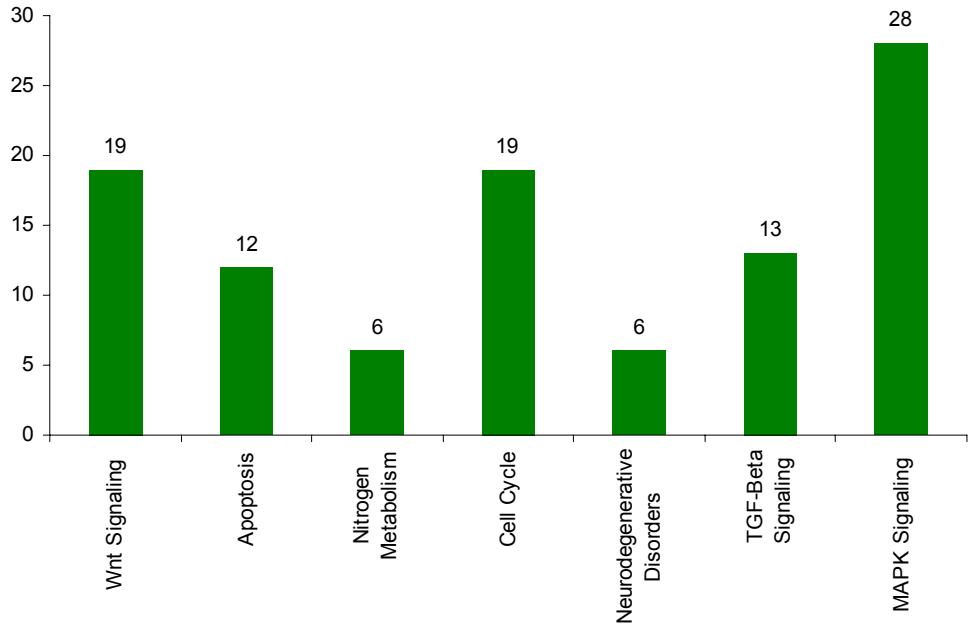

Figure 49. An overview of the number of transcripts differentially expressed in BMP-2$^+$ cell population involved in pathways, as obtained from DAVID analysis.

4.4.7 Classification of differentially expressed transcripts in BMP-2$^+$ cell in comparison to ES cells and 6day control EBs.

BMP-2$^+$ cell population represents a subset of mesoderm unlike the pan mesodermal marker, T Brachyury. Like the T Brachyury cells, BMP-2 cells also needs co-operation from other 2 germ layers for the further lineage commitment during differentiation under normal conditions. When they were kept in isolation, their interaction with the other germ layers is eliminated and hence they slow down in terms of the differentiation and remain in differentiation state between the starting ES cell state and the 6day control EBs which, are far advanced in terms of differentiation due their intact interaction with the other 2 germ layers. Hence characterization of differentially expressed transcriptome of BMP-2 population needs to be compared with both the BMP-2 ES cells and 6day Control EBs in the same way as performed for the T Brachyury transcriptome analysis. Thus the analysis will need to be addressed as follows

1. Transcripts upregulated in BMP-2$^+$ cells than both ES ells and 7day control EBs

    i. Uniquely upregulated in BMP-2$^+$ cells (Not differentially expressed among ES cells and 7day old control EBs)

    ii. Not Uniquely expressed in BMP-2$^+$ cells (Differentially expressed among ES cells and 7day old control EBs)

2. Transcripts downregulated in BMP-2$^+$ cells than both ES ells and 7day control EBs

    i. Uniquely downregulated in BMP-2$^+$ cells (Not differentially expressed among ES cells and 7day old control EBs)

    ii. Not Uniquely expressed in BMP-2$^+$ cells (Differentially expressed among ES cells and 7day old control EBs)

3. Transcripts upregulated in BMP-2$^+$ cells than ES cells but downregulated than 7day control EBs

4. Transcripts upregulated in BMP-2$^+$ cells than 7 day control EBs but downregulated than ES cells

Analysis of upregulated transcripts in BMP-2$^+$ cells in comparison to both ES cells and 7day EBs.

There are 271 transcripts upregulated in BMP-2$^+$ cells than both ES cells and 7day control EBs. Among them, there are 209 transcripts, which do not show any differential expression among ES cells and 7day EBs. The other 62 transcripts even though are upregulated than both ES cells and 7day EBs, they in turn show differential expression among ES cells and EBs. The 209 transcripts upregulated uniquely in BMP-2 cells but not differentially expressed among ES cells and EBs are the bona-fide transcriptomic signatures of BMP-2$^+$ mesodermal cells and these transcripts over-represent transcription factors and apoptosis, when analyzed with DAVID gene functional tool. The unique BMP-2 cell specific transcription factors are enlisted in table 5 and transcripts involved in apoptosis in table 6. . The transcripts upregulated in BMP-2 cells which in turn shows differential expression among ES cells and EBs did not over-represent any biological processes other than the normal physiological processes.

Downregulated in BMP-2$^+$ cells than both ES cells and 7 day control EBs

The down-regulated transcripts are categorized according to the biological processes using DAVID functional annotation tool and is shown in annexure 10. The development related transcripts are listed in annexure 11.

Upregulated in BMP-2$^+$ cells than ES cells but downregulated than 7day control EBs

54 unique transcripts were found to be upregulated in BMP-2$^+$ cells compared to ES cells but down regulated in comparison to 7d control EBs. Among the 54 transcripts, 9 transcripts are developmentally important genes as shown in the annexure 12A.

The transcripts upregulated in BMP-2$^+$ cells than 7 day control EBs but downregulated than ES cells.

There are 119 unique transcripts that are upregulated in BMP-2$^+$ cells compared to 7day EBs cells but downregulated in comparison to ES cells and development related transcripts are shown in annexure 12B. It is interesting to note that the nanog transcript is upregulated in BMP-2$^+$ cells compared to the control EBs.

4.5 CHARACTERIZATION OF αMHC$^+$ CARDIOMYOCYTES

4.5.1.Generation and analysis of the αMHC$^+$ ES cell clone

Embryoid Bodies, when made from the αMHC$^+$ ES cell clone by hanging drop protocol and analyzed at regular intervals, showed the expression of αMHC$^+$ transcripts as shown by RT-PCR in figure 50. The EGFP expressing cells were first detectable in 7-8 days old EBs and the EGFP fluorescence increases significantly after 7 days. The ES cells and EBs from this transgenic clone behaved faithfully with the wild type ES and EBs.

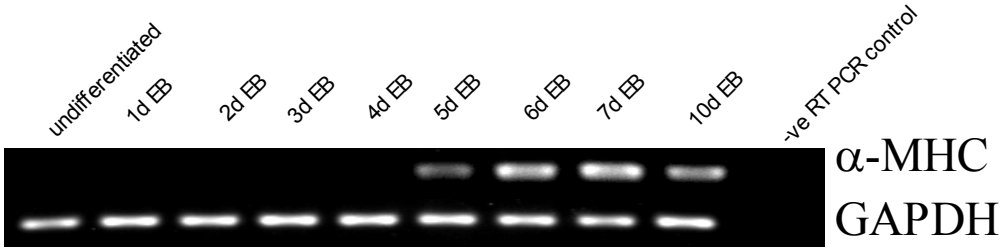

Figure 50. Expression pattern of αMHC transcript during the course of differentiation**.**

4.5.2.Isolation and transcriptomic profiling of αMHC$^+$ cardiomyocytes

The EBs were generated by hanging drop protocol. On day 7, the first contracting clusters started to appear. On the next day (day 8), the EBs were treated with or without puromycin at a concentration of 4μg/ml for the subsequent 7 days (Figure 51A). On day 15, the EBs untreated and puromycin treated were harvested by trypsinisation and analyzed with FACS to determine the purity of the cardiomyocytes in the puromycin treated cultures along with the control EBs. As shown in figure 51B, the puromycin treated cultures contained an enriched population of cardiomyocytes up to 91.15% compared to 16.72% of the control EBs. Thus an enrichment of the pure cardiomyocytes by 5.5 fold compared the control EBs was obtained by this approach. RNA was isolated from these cardiomyocytes for the transcriptomic profiling by Affymetrix.

The αMHC$^+$ cardiomyocytes thus derived from the ES cells were analyzed by immunohistochemistry. They showed a multi-angular (Fig. 52a and b), more rectangular (Figure 52c and d) and a tri-angular morphology (Figure 52e and f). Detection of cardiac α-actinin by immunocytochemistry (Figure 52b, d and f) clearly indicated the Z-disc specific protein and the characteristic striations of sarcomeric structures of the cardiac cells. The gap junction protein Connexin43 is highly expressed in the heart and was detected by immunocytochemistry (Figure 52g and h). Connexin43 is distributed in the cytosol and in the outer membranes in the cell border regions (Figure 52g and h, middle panel).

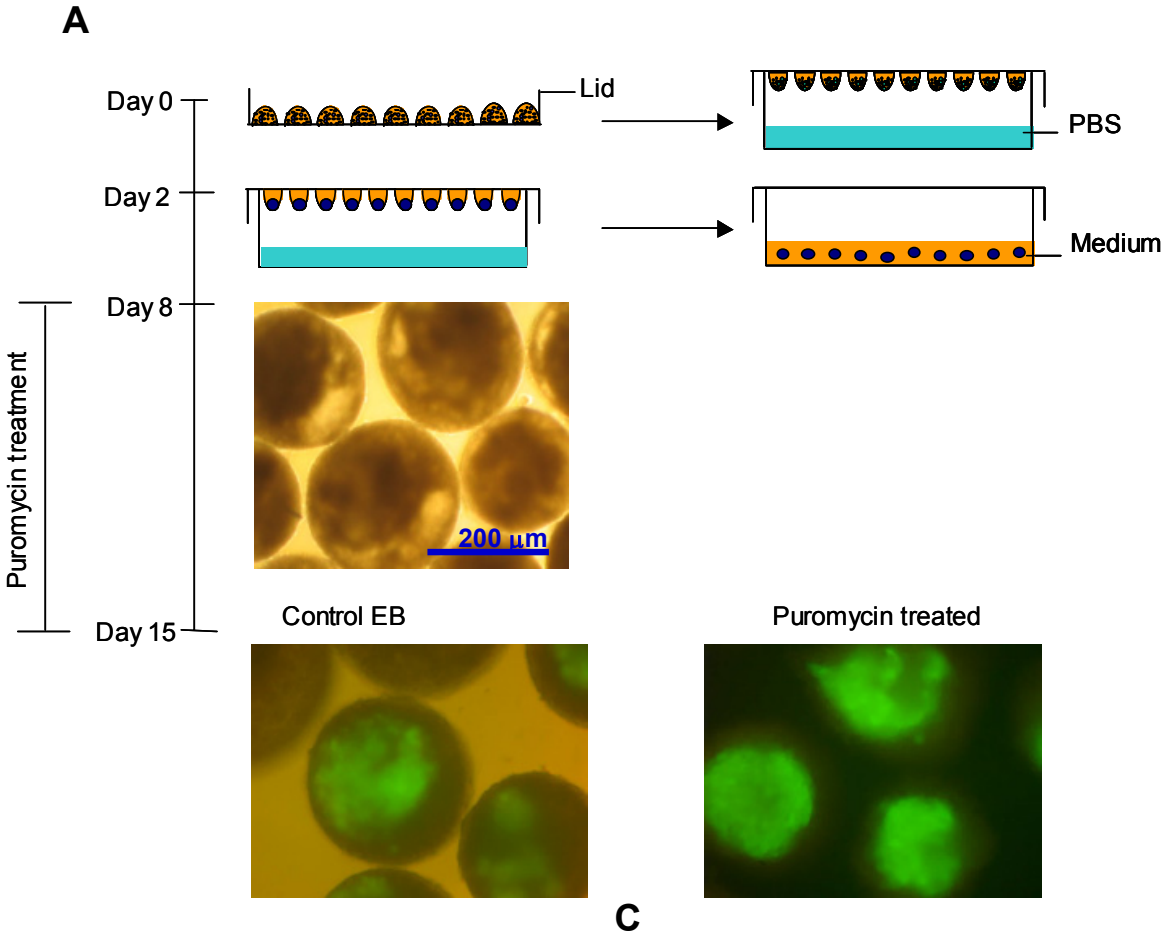

Figure 51. Enrichment of αMHC$^+$ cells isolated from the αMHC+ ES cell lineage after puromycin treatment. **A,** progressive purification of αMHC+ cardiac cell aggregates after treatment of the 8-days old EBs with 4µg/ml puromycin for 7 days. Puromycin containing medium was refreshed every second day. **B, C,** Cells from 15-days old EBs and 15-days old puromycin purified αMHC$^+$ aggregates were dissociated by trypsinisation and the purity of the αMHC$^+$ cells in the 15-days old EBs (C) and in the 15-days old αMHC$^+$ aggregates (D) was examined by FACS analysis.

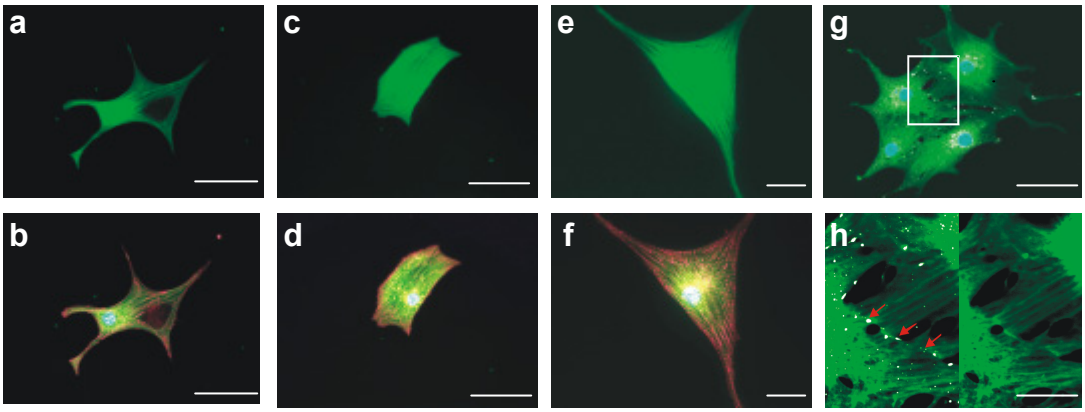

Figure 52. Characterization of the ES cell-derived cardiomyocytes by immunocytochemistry. αMHC$^+$ cardiomyocytes were dissociated with collagenase B and plated on fibronectin coated cover slips. (a, c, e) EGFP expression of single αMHC$^+$ cells with different morphology. (b, d, f) Detection of α-cardiac actinin and Connexin43 (g, h) was performed using anti-cardiac Actinin (1:400) and anti-Connexin43 1:400. Secondary detection was performed with anti-mouseIgG1-AlexaFluor555 and anti-rabbit-Ig-AlexaFluor647. Hoechst dye was used to stain nuclei. Bars in (a-f) represent 50 and bars in (g) 20 and (h) 7.5 µm.

4.5.3 Electrophysiological characterization of the cardiomyocytes

Functional characterization of the αMHC$^+$ cardiac cells has been performed by measurements of their typical spontaneous action potentials (APs). Spontaneous APs were measured in single αMHC$^+$ cardiomyocytes (n=32) as well as in multicellular αMHC$^+$ aggregates (n=24). All APs possessed characteristic parameters of cardiac APs. The minimal diastolic potential was -60.2±1.1 mV, membrane potentials normally showed a diastolic depolarization leading to a spontaneous AP frequency of 125.9±8.0 /min. The maximal upstroke velocity was 22.9±2.2 V/s, pointing to a contribution of voltage-activated Na^+ currents, which was confirmed by voltage-clamp measurements (data not shown). APD_{90}, APD_{50} and APD_{20} (AP duration from maximum to 90%, 50% and 20% repolarization) were 96.4±4.2 ms, 71.1±3.9 ms and 41.3±2.6 ms. APs had a variety of morphologies, including pacemaker-, atrial- and ventricular-like APs (Figure 53). In most cases, however, morphological properties did not match any type of specific differentiation. These unspecified APs mostly possessed a plateau phase, but had a much shorter APD_{90} than ventricular APs, which are characterized by a long APD_{90} of about 200 ms [112].

To characterize the hormonal regulation of αMHC cardiomyocytes, carbachol (Cch, an agonist of m-cholinoceptors), and isoproterenol (ISO, an agonist of β_1-adrenoceptors), were applied (Figure 53B and C). 1 µM Cch decreased the AP frequency significantly to 44.8±7.5 % of the control values (n=20; the frequency under control conditions was

determined for each recording and set to 100; Figure. 53D). 1 µM ISO evoked a significant increase of the frequency to 238.5±23.7 % of the control values (n=19; Fig. 2E). Intracellular recordings of spontaneous APs revealed typical cardiac AP parameters and morphologies confirming the cardiac differentiation and functionality of puromycin-selected αMHC$^+$ cells. The muscarinic and adrenergic regulation of the AP frequency, which is known for ES cell-derived cardiomyocytes [113] as well as for native murine cardiomyocytes at early developmental stages [114], further supports a physiological cardiac differentiation of αMHC cells. As described previously [115,116], APs at the intermediate developmental stage showed diastolic depolarizations and diverse shapes. APs with a distinct plateau phase were frequent but considered to be unspecific rather than ventricular-like in the majority of cases, since the APD_{90} was much shorter than reported for early stage murine ventricular cardiomyocytes as well as for murine ES cell-derived ventricular-like cardiomyocytes [117]. Since most APs had unspecific morphological properties, a general classification into pacemaker-like, atrial-like and ventricular-like APs could not be made, which accords well with previous findings from intermediate stage ES cell-derived cardiomyocytes [118,119]. Only few APs possessed typical morphological features of the respective differentiation types.

It has been reported recently that, in ES cell-derived cardiomyocytes expressing GFP under control of the αMHC promoter, green fluorescence is restricted to pacemaker- and atrial-like cells [120]. Since we found puromycin-purified αMHC$^+$ cardiomyocytes with a ventricular-like AP morphology in few cases, our data suggest that αMHC expression is not completely absent in ES cell-derived ventricular-like cardiomyocytes. This apparent discrepancy might arise from the complex stage-dependent expression pattern described for αMHC in murine embryoid bodies [121] and murine embryonic ventricles [122], as a different developmental stage of ES cell-derived cardiomyocytes was investigated in the present study (15-day old cardiomyocytes) as compared to the study by Kolossov et al. (9-day to 11-day old cardiomyocytes) [123].

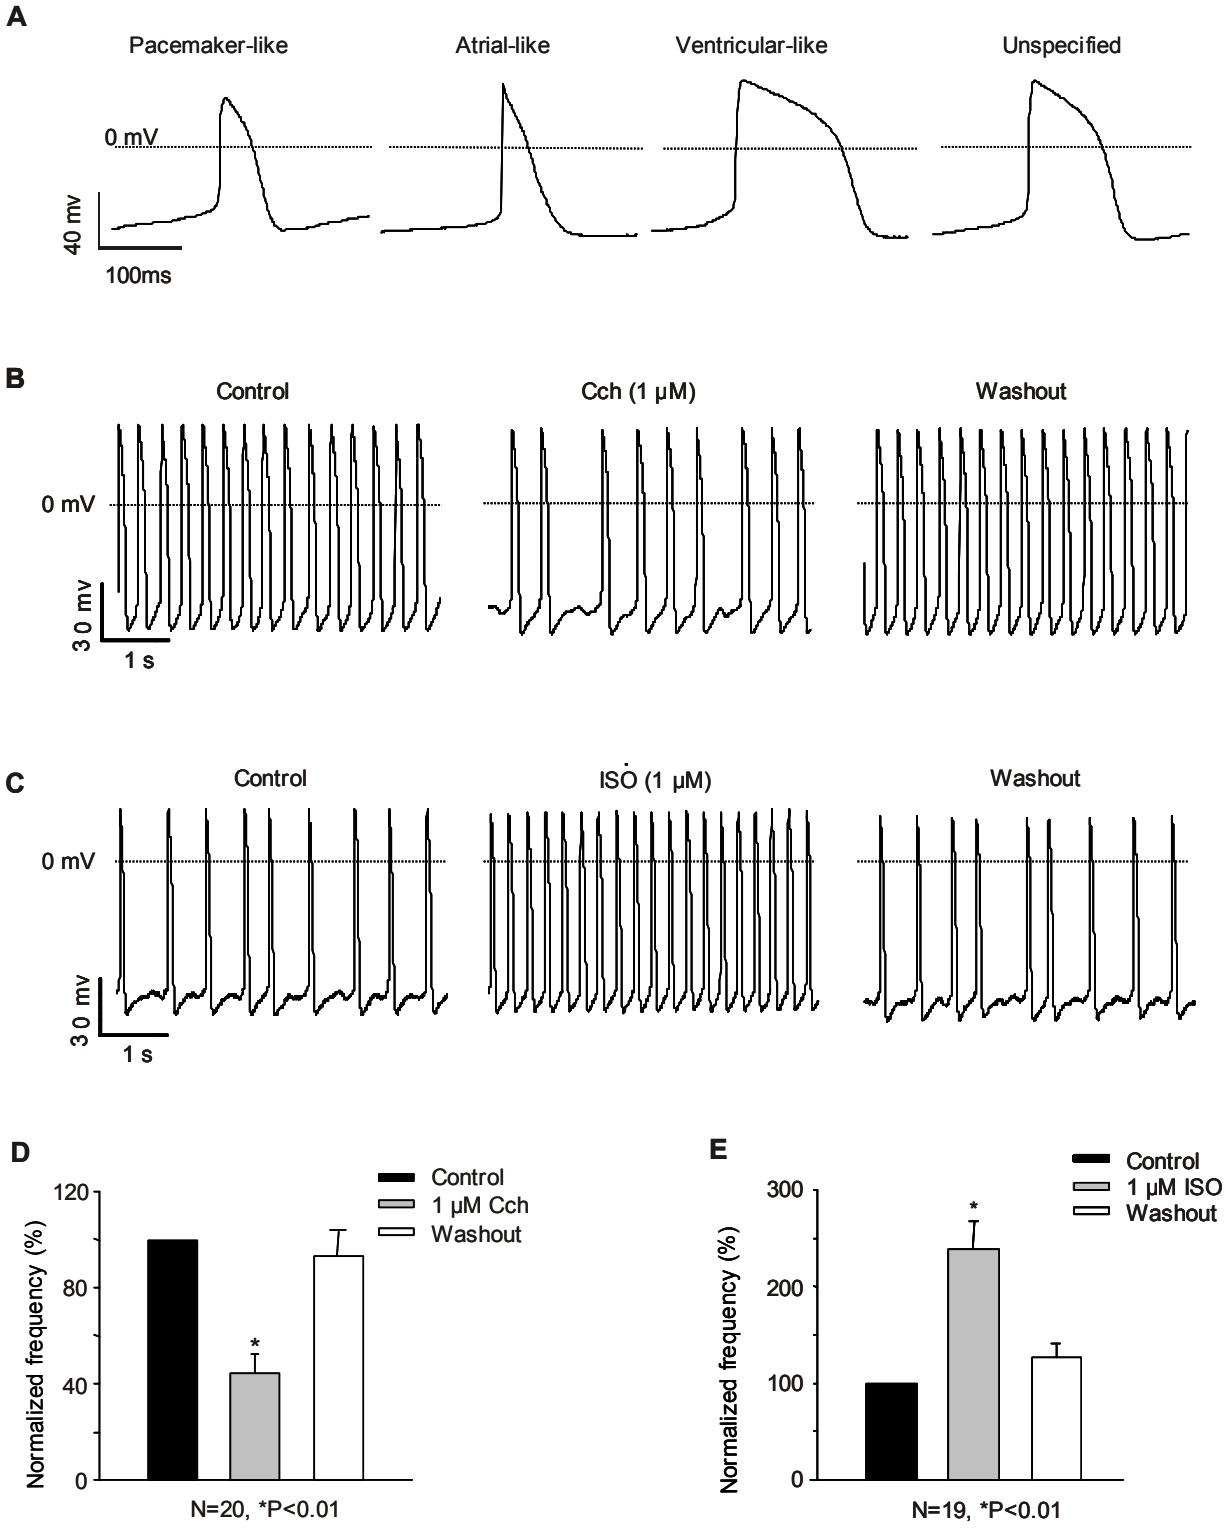

Figure 53. Electrophysiological characterisation of αMHC+ cells. **A,** Characteristic cardiac APs of puromycin purified αMHC cells. Most APs had a typical cardiac AP morphology but could not be further specified. Only few APs showed typical features of pacemaker-like atrial-like or ventricular-like APs. The minimal diastolic potential was –60.2±1.1 mV. The maximal upstroke velocity was 22.9±2.2 V/s. APD_{90}, APD_{50} and APD_{20} were 96.4±4.2 ms, 71.1±3.9 ms and 41.3±2.6 ms. **B, C,** Representative recordings showing the effect of Cch (1 µM) (B) and ISO (1 µM) (B) on the spontaneous AP frequency. **C, D,** Statistical analysis of the effects of Cch (1 µM) and ISO (1 µM), respectively, on the spontaneous AP frequency. Cch caused a decrease while ISO increased the spontaneous AP frequency.

4.5.4.Validation of Affymetrix data by quantitative real time PCR

The affymetrix data obtained from the ES cells, 15 days old puromycin treated and untreated αMHC EBs were verified by quantitative real time PCR analysis of the pluripotent and germ layer specific genes –Nanog, T- Brachyury, BMP-2, Neurofilament H, Sox 17 and a- myosin heavy chain. As seen in the figure 54, the Real time PCR data correlated very well with the affymetrix data. Additionally, the cardiomyocyte specific markers were analyzed in these samples by semi-quantitative PCR (Figure 55).

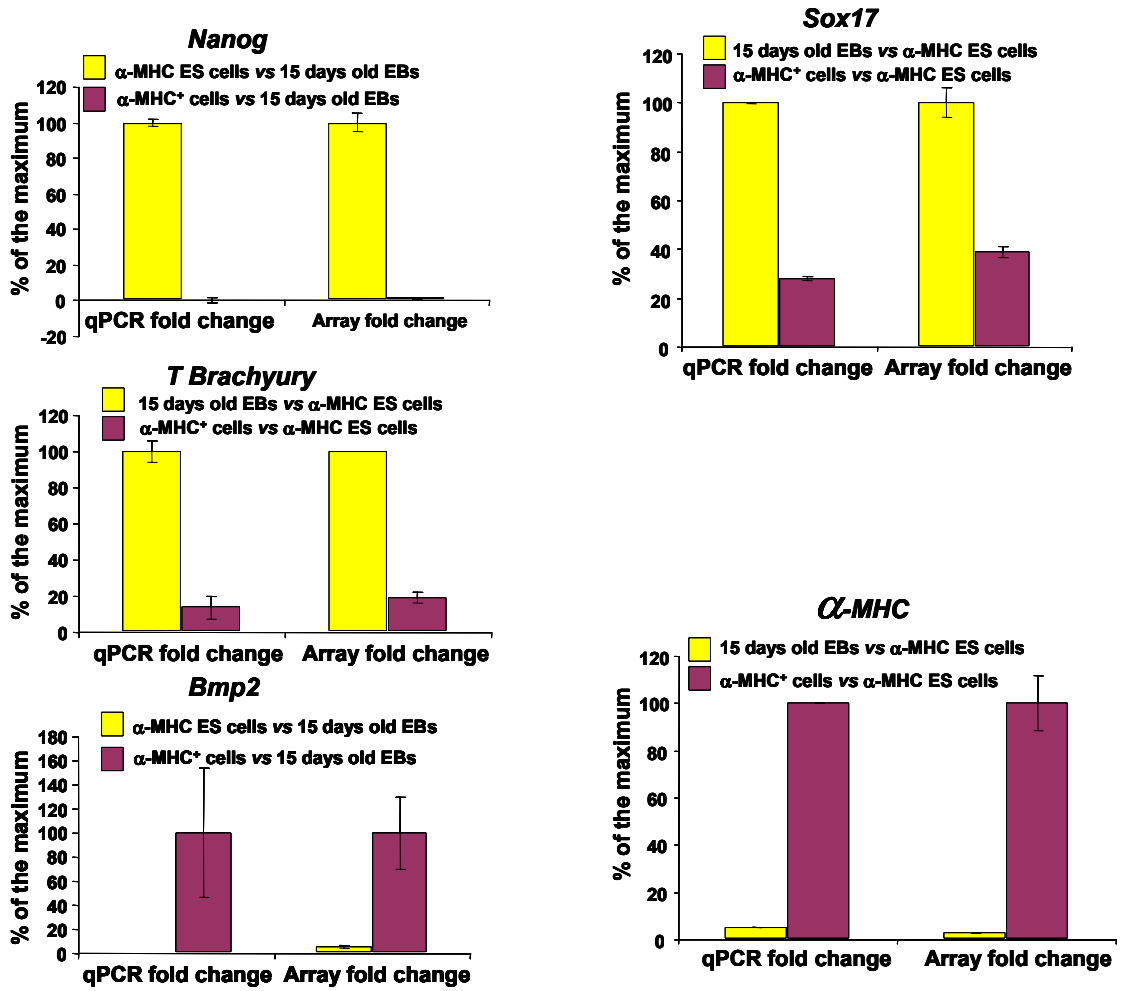

Figure 54. Validation of the Affymetrix data by Quantitative real-time PCR analysis of 5 representative genes. The fold change was calculated by using the formula, fold-change = $2^{-(\Delta C_t \text{ gene1} - \Delta C_t \text{ gene2})}$. ΔC_t of the gene in the sample in which it is expressed lowest is taken as ΔCt gene2 to calculate the fold change using the above formula. The resulting fold change is expressed as percentage of the maximum (=100%).Values are expressed as mean ± SD.

4.5.5.Transcripomic analysis of αMHC$^+$ cardiomyocytes

To rule out the differentially expressed transcripts are specific to cardiomyocytes and are not due to the puromycin application, under the same experimental conditions as for the derivation of cardiomyocytes, on day 8 the EBs were either treated with puromycin or untreated for the subsequent 7 days. On day 15, the RNA samples were prepared from the β actin ES cells, 15 day old puromycin treated β actin EBs and untreated control βactin EBs. The samples were affymetrix profiled in the same way as for the αMHC samples.

As the first step, the differentially expressed genes due to puromycin treatment were analyzed. There were 235 unique transcripts with student t-test value of $p<0.01$ among the transcripts differentially expressed among puromycin treated β actin EBs and untreated control βactin EBs and these transcripts were excluded from the analysis of the αMHC transcriptome.

Overall, there are 7700 unique transcripts differentially expressed in αMHC$^+$ cardiomyocytes (2 fold up or 2 fold down with an ANOVA p value cut off of 0.01) compared to either the αMHC ES cells or 6day old control EBs. Among these transcripts, 1315 transcripts with ANOVA p value <0.01 are participating in pathways as shown in the annexure 13 and this comprises 17.08% of the 7700 unique transcripts differentially expressed in αMHC$^+$ cardiomyocytes. It is not surprise to see a significant number of transcripts differentially expressed that are participating in oxidative phosphorylation. This process is essential for the cardiomyocytes to derive the energy for their contraction. Strikingly 128 transcripts participate in MAPK signaling pathway, 68 transcripts in Wnt Signaling and 52 transcripts in TGFβ signaling pathways as shown in the figures 56,58-62. Among the 7700 transcripts differentially expressed in αMHC$^+$ cardiomyocytes in comparison to αMHC ES cells and 15 day αMHC control EBs, 873 genes are implicated in embryonic development as shown in Figure 57.

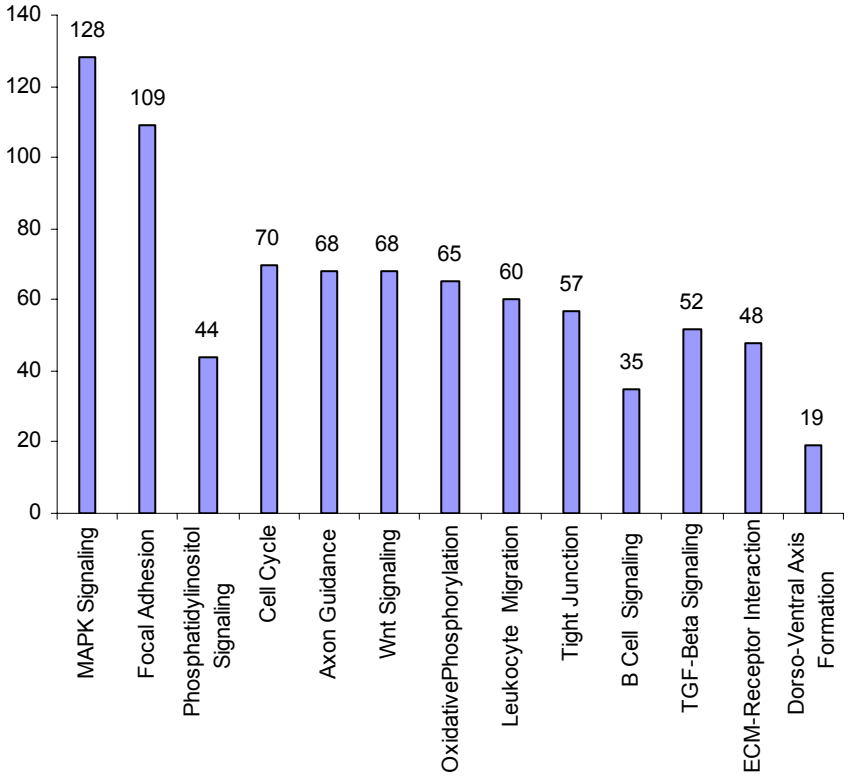

Figure 56. List of the transcripts that are differentially expressed in cardiomyocytes and are involved in pathways in comparison to ES cells, 15day old EBs or both. The count represents the relative ratio of the transcripts belonging to the particular pathway to the total transcripts differentially expressed in cardiomyocytes.

2. Transcripts downregulated in αMHC$^+$ cardiomyocytes than both ES ells and 15 day control EBs
    i. Uniquely downregulated in αMHC$^+$ cardiomyocytes (Not differentially expressed among ES cells and 15-days old EBs)
    ii. Not Uniquely expressed in αMHC$^+$ cardiomyocytes (Differentially expressed among ES cells and 15-days old EBs)
3. Transcripts upregulated in αMHC$^+$ cardiomyocytes than ES cells but downregulated than 15 day control EBs
4. Transcripts upregulated in αMHC$^+$ cardiomyocytes than 15 day control EBs but downregulated than ES cells

Analysis of upregulated transcripts in αMHC$^+$ cardiomyocytes in comparison to both ES cells and 15-day-old EBs

There are 1319 transcripts upregulated in αMHC$^+$ cardiomyocytes than both ES cells and 15 day control EBs. Among them, there are 927 transcripts, which do not show any differential expression among ES cells and 15day old control EBs. The other 392 transcripts even though are upregulated than both ES cells and 15 day old EBs, they in turn show differential expression among ES cells and EBs. The distribution of the transcripts according to Gene Ontology “Biological Process” by David Bioinformatics resource analysis is presented in the figure 63. The 927 transcripts upregulated uniquely in αMHC$^+$ cardiomyocytes but not among ES cells and EBs are the bonafide transcriptomic signatures of αMHC$^+$ cardiomyocytes. As seen from the figure 63B, the transcripts of cardiomyocyte transcriptome are involved in the cardiac specific physiological processes like ATP synthesis and oxidative phosphorylation. There are 81 αMHC$^+$ cardiomyocytes specific transcripts involved in development according DAVID analysis and are enlisted in table 8. Among the transcripts upregulated in αMHC$^+$ cardiomyocytes which in turn show differential

expression among ES cells and EBs, the 18 transcripts involved in developmental processes are listed in the annexure 14. 8 transcripts are involved in MAPK signaling pathway and 10 transcripts in calcium signaling pathway (annexure 15).

Downregulated Transcripts in αMHC⁺ cardiomyocytes than both ES cells and 6day control EBs

There are 1444 unique transcripts downregulated in αMHC⁺ cardiomyocytes than both ES cells and 15 day control EBs. Of them, there are 939 transcripts uniquely downregulated in αMHC⁺ cardiomyocytes cells which do not show any differential expression among ES cells and 15 day EBs. Those transcripts categorized according to the biological process they mediate are shown in figure 65. Apart from that, 494 transcripts are downregulated than both ES cells and 6d EBs but in turn show differential expression among ES cells. The developmental related transcripts are listed in annexure 16.

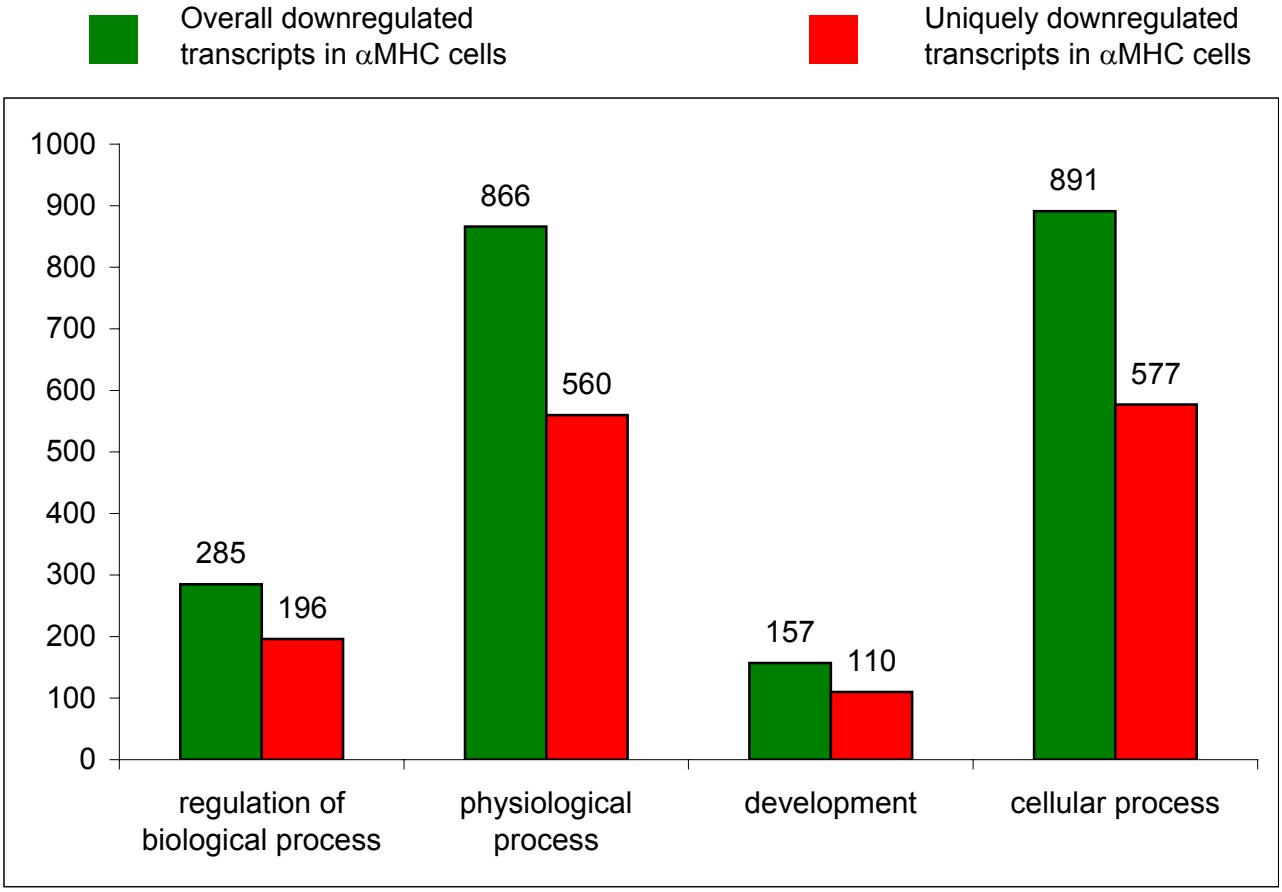

Figure 65. The major biological processes overrepresented by the transcripts downregulated than both ES cells and 15day EBs (green bar) and unique αMHC⁺ cardiomyocytes specific transcriptome downregulated in comparison to ES cells and 15-day cardiomyocytes (in red bar).

Transcripts upregulated in αMHC cardiomyocytes than ES cells but downregulated than 15 day control EBs

243 unique transcripts were found to be upregulated in αMHC cardiomyocytes compared to ES cells but down regulated in comparison to 15day control EBs. Among the 243 transcripts, 56 transcripts are developmentally important genes as shown in the annexure 17.

The transcripts upregulated in αMHC cardiomyocytes than 15 day control EBs but downregulated than ES cells.

There are 22 unique transcripts that are upregulated in αMHC^{+} cells compared to 15-day EBs cells but downregulated in comparison to ES cells (annexure 18).

4.6 FUNCTIONAL EVALUATION OF NOVEL TRANSCRIPTS

4.6.1 Experimental approach

Three novel candidate genes whose functions have not yet been annotated but highly enriched in $BMP\text{-}2^{+}$ cell lineages were chosen after assessing the pattern of transcript expression in differentiating EBs. Since the differentiating EBs can not be transfected efficiently with siRNA with non-viral delivery methods due to their multicellular 3 dimensional aggregations, the transcripts that are expressed even in the undifferentiated pluripotent state were specifically chosen. These transcripts were functionally evaluated by a systematic “loss of or gain of function“ studies using siRNA knockdown approaches and episomal overexpression systems.

The T Brachyury ES cell clone were transfected with siRNAs targeted to each of these novel transcripts. At 48 hours post transfection, the transfected ES cells were used for making “hanging drop” EBs and followed up. RNA were isolated at 24 hours post transfection, and just before making hanging drop EBs (48 hours post transfection) and then at regular intervals at days 3, 5 and 7, the time points at which T Brachyury, BMP-2 and αMHC peak their transcripts expression respectively (Figure 66) and on day 9. The RNA isolated were analyzed for magnitude of expression by the germ layer representative and other genes, *Nefh* (ectodermal marker), *T brachyury* (mesodermal marker), *BMP-2* (mesodermal marker), *Sox17* (endodermal marker), *Nanog (*pluripotent ES cells marker) and *αMHC* (cardiomyocyte marker, actual gene name is *Myh6*). siRNA transfected ES cells were monitored for any morphological changes associated with any differentiated cell types. On day 4, T Brachyury driven EGFP was quantified by FACS analysis as an index of mesodermal cells formed within the siRNA transfected EBs.

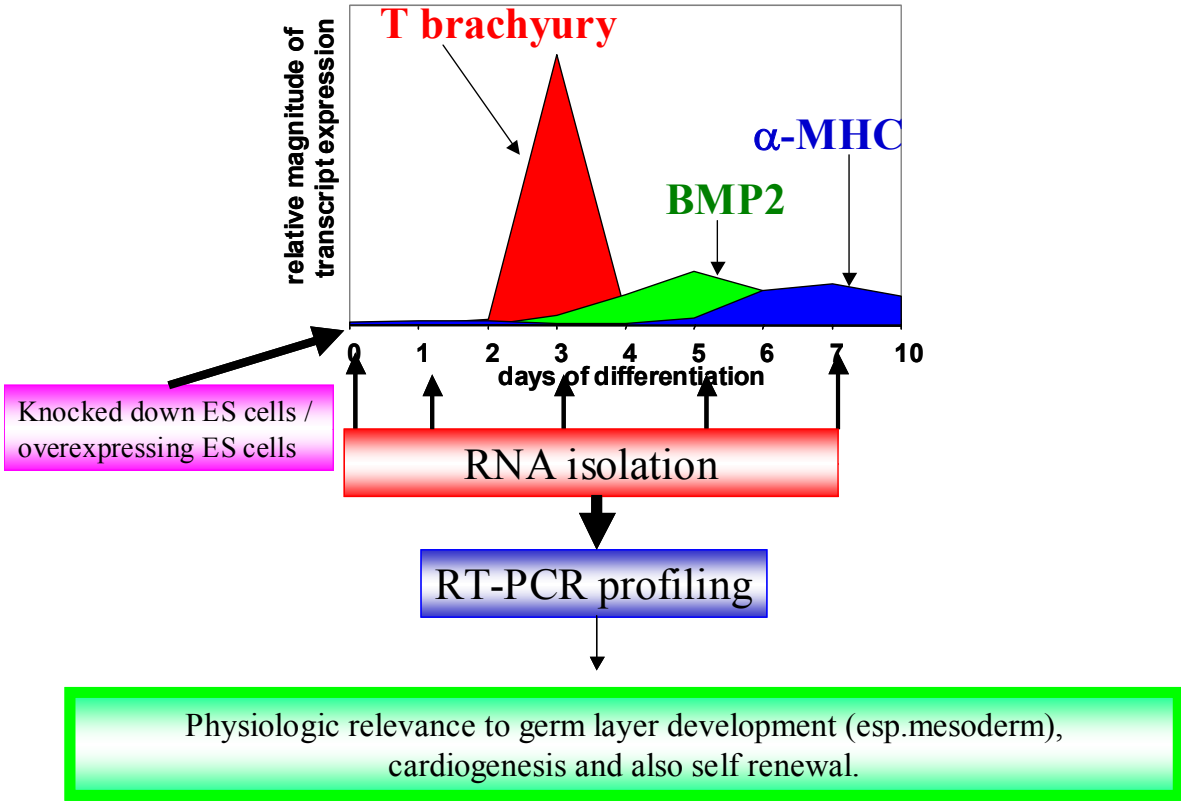

Figure 66 Overview of the experimental approach to functionally evaluate the novel transcripts using ES cells with siRNA knock down ("loss of function") and "gain of function" approaches.

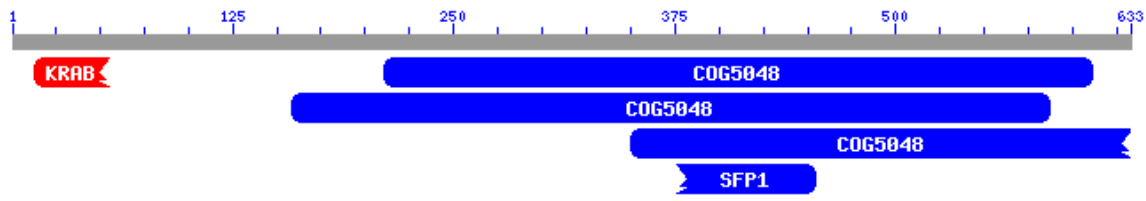
4.6.2 The candidate genes- overview and results

1. MGC117846 (Similar to zinc finger protein 665)

This transcript is a putative transcription factor (for NCBI details, please see annexure 19) . It contains the single conserved domain each of krueppel associated box and SFP1 (Putative transcriptional repressor regulating G2/M transition) and multiple conserved domains of Zn-finger as shown in figure 67. During the early embryonic development, this transcript expression is developmentally regulated as seen in figure 70. In the ES cell/EBs system, this transcript is expressed at highest level in the undifferentiated ES cells and as its expression start to decline, the BMP-2 transcript start to be expressed (Figure 68). The fold changes in comparison to ES cells and the respective control EBs as obtained from the transcriptomic profiling of T Brachyury and BMP-2 lineages cells are shown in the figure 69. So, being a transcription factor expressed in pre-implantation stage and mid-gestation embryos and its downregulation precedes BMP-2 transcript expression, it may be likely that this transcript may have an influence on BMP-2 expression since this transcript is highly expressed in ES cell-derived BMP-2^{+} lineage cells. Hence this candidate was chosen for the functional evaluation to check whether this transcript has any inhibitory effect

on BMP-2 expression. The nucleotide and protein sequence information are shown in the



KRAB = krueppel associated box;
COG5048 = FOG: Zn-finger [General function prediction only].
SFP1 =Putative transcriptional repressor regulating G2/M transition

1700108L22Rik

This is RNA binding protein that is developmentally regulated in early embryonic stages as shown in figure 74. The NCBI details for this gene are presented in annexure 20. This transcript is enriched in pre-implantation embryos. The function of this gene has not yet been reported even though it is guessed from the LA domain contained in this gene that this codes for a protein which binds to RNA. Generally La protein plays a role in the transcription of RNA polymerase III. It is most probably a transcription termination factor. Binds to the 3' termini of virtually all-nascent polymerase III transcripts. It is associated with precursor forms of RNA polymerase III transcripts including tRNA and 4.5S, 5S, 7S, and 7-2 RNAs (By similarity). Since this transcript is temporally and spatially regulated during development and also upregulated in the T brachyury and BMP-2 cell lineages, this gene was chosen assuming that the rest of the protein apart from the La domain may be playing any role especially modulating the BMP-2 transcription as shown in the Figure It is interesting to note pattern of this transcript in comparison to BMP-2 transcripts that the downregulation of this transcript is coupled with the up regulation of BMP-2 transcript.

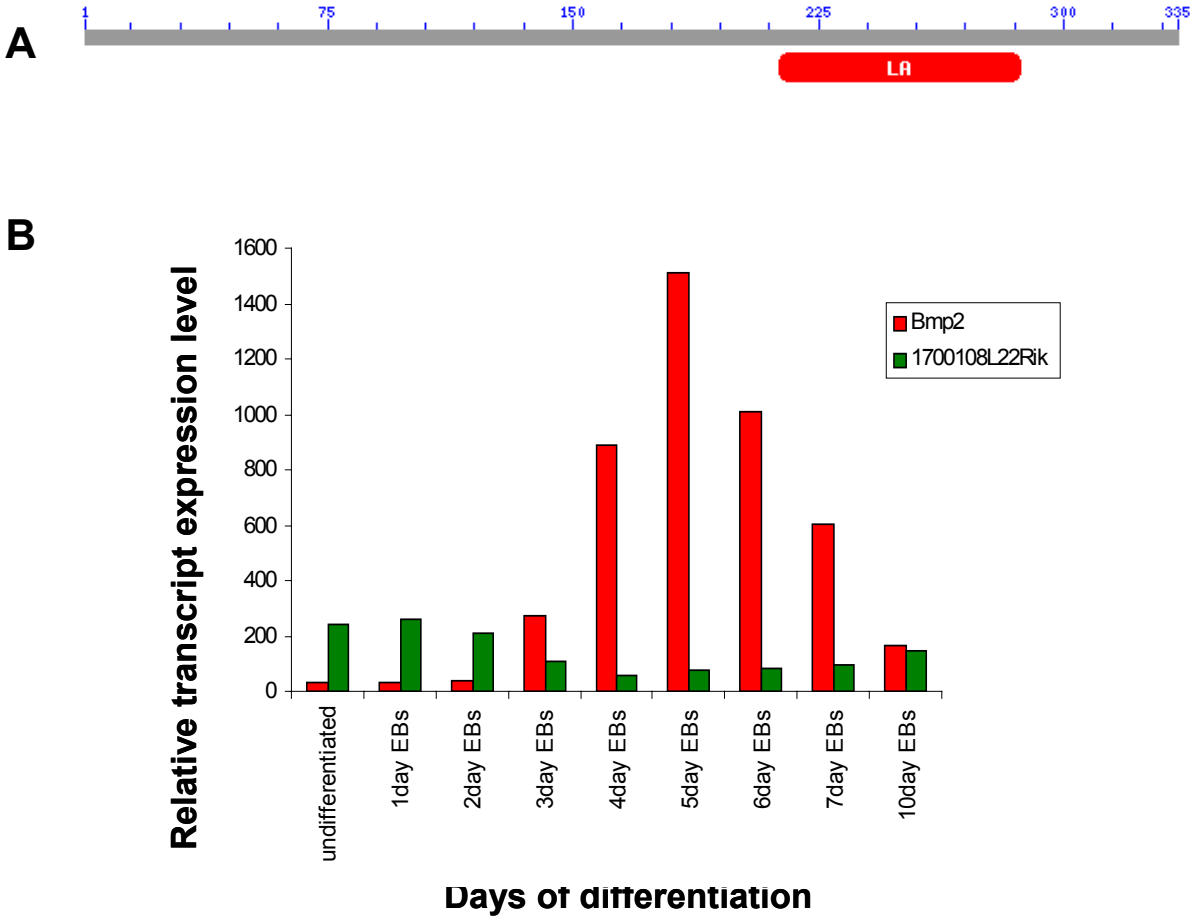

Figure 72 A. Conserved LA domain contained in the *1700108L22Rik.* B., Expression of *1700108L22Rik* transcript during the course of differentiation.

B

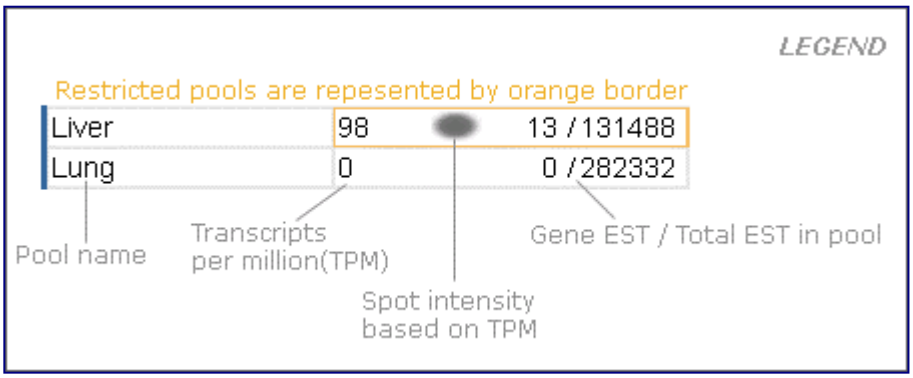

Figure 74. A., Developmental stage specific expression of *1700108L22Rik* transcript. **B.**, Legend.

siRNA knockdown of 1700108L22Rik

Knockdown by siRNA targeted against *1700108L22Rik* did cause a down regulation of BMP-2 transcripts on day 3. Apart from that, it did not cause any significant effect as shown in the figure 75. There were no morphological differences observed. The down regulation of the BMP-2 transcript by the knockdown of the 1700108L22Rik shows a positive interaction between these 2 transcripts. But in comparison to the time kinetics in differentiating EBs, there is reciprocal interaction may be inferred. This needs to be addressed further since there are several modes of auto-regulatory mechanisms existing. But there were no effects when over-expressed. So, this has to be addressed this contrary situation.

Episomal overexpression of 1700108L22Rik

Full Length cDNA Clone IRAVp968A0470D encoding the *1700108L22Rik* was purchased from RZPD, Germany and the *1700108L22Rik* cDNA was subcloned into the pPyCAGIP over expression plasmid. The resulting plasmid was transfected into T Brachyury ES cell clone and generated the overexpression clone. Hanging drop EBs made from the EBs were analyzed in terms of the lineage specific transcript levels including BMP-2. There was no significant effect was observed as shown in figure 76.

Gm397

It is a novel transcript predicted by electronical models as shown in annexure 21. It is a very interesting gene since its expression is uniquely restricted to pre-implantation embryo and pluripotent undifferentiated ES cells (Figure 77 And 78). This gene was selected under the assumption that it might be involved in the maintenance of ES cell pluripotency. It is still a hypothetical protein, even then the transcripts are expressed and its mRNA sequence information is known. The protein has one leucine rich domain and shows zinc ion binding sites and electronically annotated to be a transcription factor. But in the development context, the function of this gene is still unknown even though they are enriched in the ES cells. This transcript is highly enriched in T Brachyury and BMP-2 lineage cells, unlike Pou5f1 *(Oct4),* the pluripotent associated marker.

5.Conclusion and Outlook

Conclusion and Outlook

The transcriptomic analyses of the mesodermal cells and cardiomyocytes have defined unique cellular and genetics identities of the respective lineages towards understanding the inducible fate of mesodermal patterning and predicting to some extent how the prospective mesodermal cells integrate the various signals they receive and how they resolve this information to regulate their morphogenetic behaviors and cell-fate decisions. They in turn significantly contribute in building lineage specific transcriptomic atlas, which will be of immense application for the developmental biologists and also for promoting the protocols for the derivation of selective lineages for the future cell replacement therapy.

The isolated T Brachyury^{+} and BMP-2^{+} cells are able to prime themselves to become cardiomyocytes. While the ES cell-derived T Brachyury lineage also gives rise to endodermal lineages, the BMP-2^{+} lineages are completely devoid of any endodermal derivatives. In addition, early BMP-2^{+} lineages exhibit neural crest stem cell properties. Thus, while T Brachyury cells represent lineage non-committed early stage mesodermal cells, BMP-2 cells represent the late stage mesodermal population that can autonomously give rise to cardiomyocytes and are already lineage committed. Comparison of both the lineages points out that they exhibit certain plasticity at the early stage. Even the T Brachyury^{+} cells can be maintained in culture for longer time with optimal amount of Leukemia inhibitor factors (LIF) and simultaneous puromycin selection. The EBs made from these cultures gave rise to contracting cardiomyocytes, even though the process of cardiomyogenesis was delayed. This represents a model to study patterning of mesodermal cells into cardiomyocytes in a selective approach without starting from ES cells in which case, the interplay of the ectodermal derivatives in mesodermal patterning would make the investigation very complex. In addition, the transcriptomic analysis of T Brachyury cells characterizes the cellular and genetics identity of the mesodermal cells, which have not yet been reported till date. This would significantly complement the better understanding of the mesodermal patterning. In vitro ES derived BMP-2^{+} cell population contains neural crest stem cells and their derivatives-smooth muscle cells, melanocytes, cardiomyocytes and vascular and hematopoietic progenitors. Enrichment of the neural crest cells and their lineages by BMP-2 promoter driven selection marker paves the way for ES cell-derived neural crest stem cell biology. These cells are the attractive candidates for the future cell replacement therapy due their plasticity into any tissue depending upon the local environment existing within the injected tissue. This study enlists the cells expressing BMP-2 and gives an initial clue how these BMP-2 secreting cells play an important role during the development. The characterization of ES cell-derived cardiomyocytes proves that they

behave more or less similar to native *in vivo* cardiomyocytes in terms of the transcripts involved in physiological processes and other development processes.

The future approach will be to further analyze the transcripts to elucidate the underlying mechanisms using several approaches like finding the preferred transcription binding sites by most of the transcription factors to get a clue about the molecular details about the mesodermal patterning. The novel transcripts whose functions have not yet been annotated but enriched in these lineages have to be functionally decoded to fill up the missing links in the developmental process by loss of function and gain of function studies using ES cells and also *in vivo* zebra fish models. In addition, the T Brachyury^{+} cells can be used as starting culture for directing into cardiomyocytes to decipher the molecular mechanisms of cardiomyocytes more closely in an efficient way.

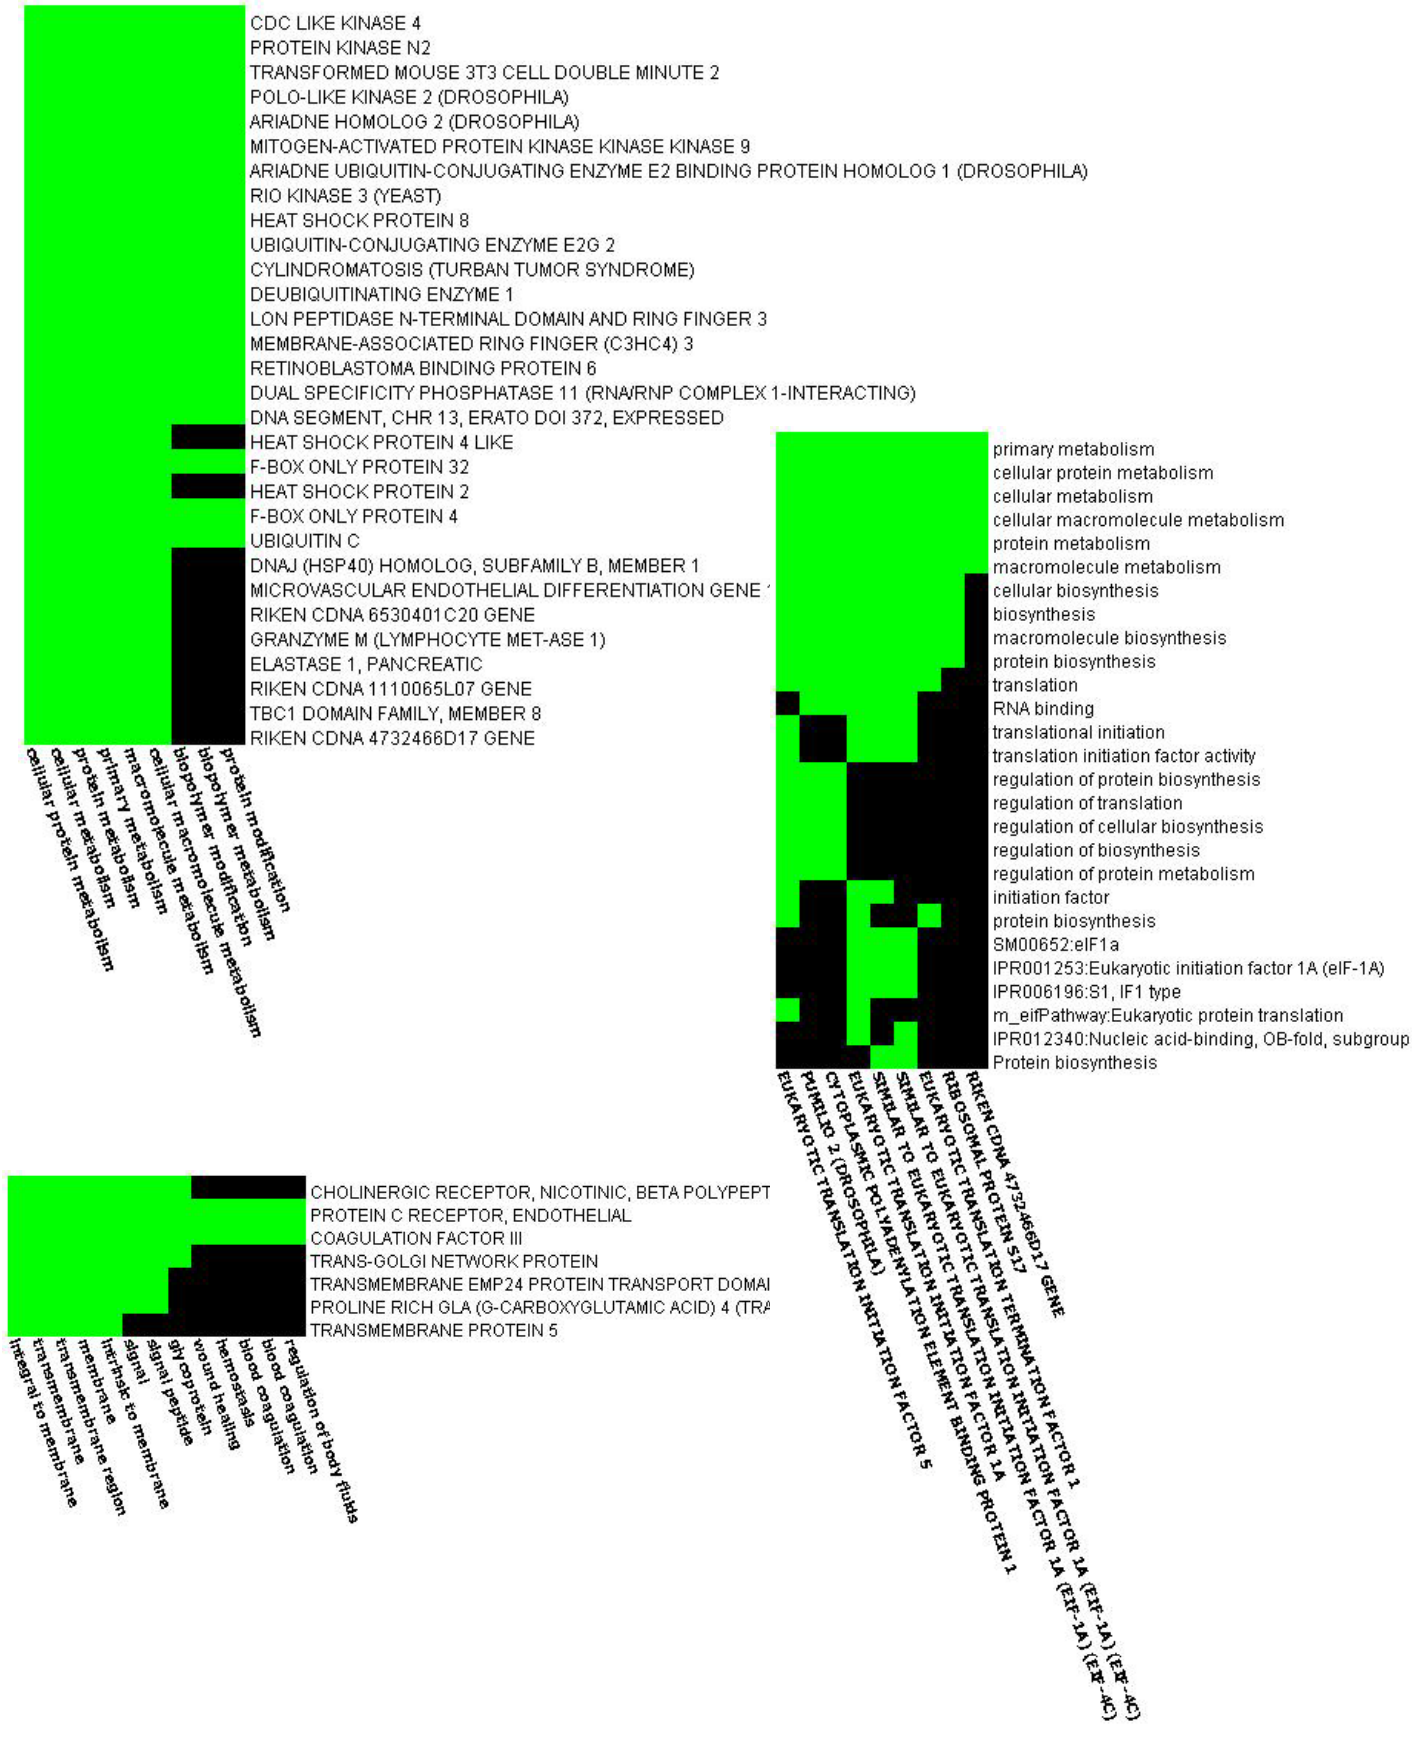
Annexure-2

Heat map of the transcripts upregulated specifically in T Brachyury^{+} cell population that are not included in GOs of development , transcription and signaling.



Annexure-3

Development related transcripts that are upregulated in T Brachyury$^+$ cells than ES cells and 6d control EBs but show differential expression among ES cells and 6 day EBs. The fold change is expressed relative to the lowest value of expression that is normalized to 1.

Annexure-18

Developmental related transcripts that are upregulated in α MHC $^{+}$ more than the 15d control EBs but downregulated than the ES cells. The fold change is expressed relative to the lowest value of expression that is normalized to 1.

```
LOCUS       NM_001013765            2276 bp    mRNA    linear   ROD 18-NOV-2006
DEFINITION  Mus musculus gene model 397, (NCBI) (Gm397), mRNA.
ACCESSION   NM_001013765 XM_142517
VERSION     NM_001013765.2  GI:118131157
KEYWORDS    .
SOURCE      Mus musculus (house mouse)
  ORGANISM  Mus musculus
            Eukaryota; Metazoa; Chordata; Craniata; Vertebrata; Euteleostomi;
            Mammalia; Eutheria; Euarchontoglires; Glires; Rodentia;
            Sciurognathi; Muroidea; Muridae; Murinae; Mus.

  TITLE     Antisense transcription in the mammalian transcriptome
  JOURNAL   Science 309 (5740), 1564-1566 (2005)
   PUBMED   16141073
COMMENT     PREDICTED REFSEQ: The mRNA record is supported by experimental
            evidence; however, the coding sequence is predicted. The reference
            sequence was derived from AC166368.3.
            On Nov 17, 2006 this sequence version replaced gi:62000641.

            Sequence Note: The RefSeq transcript and protein were derived from
            genomic sequence to make the sequence consistent with the reference
            genome assembly. The genomic coordinates used for the transcript
            record were based on transcript alignments.

Curriculum Vitae

Name : Michael Xavier Doss.J

Address : Simmerer Strasse 27,
50935 Cologne.
Germany.

Permanent address : 3/603 Bagath Singh Road,
Paramakudi-623707.
Tamil Nadu.
India.
Email: xavi7677@yahoo.com

Date of Birth : 7th June 1978.

Nationality : Indian

Schooling

1983-1988	Primary School Studies	Paramakudi, India
1988-1993	Secondary School Studies	Paramakudi, India
1993-1995	Higher Secondary School Studies	Paramakudi, India

College/University Education:

1995-1998	Bachelor of Science in Biochemistry	Madurai Kamaraj University, India.
1998-2000	Master of Science in Biotechnology	University of Calicut, India.
2000-2001	Pre-Ph.D course work	Jawaharlal Nehru University, India.

Research

2001-2002 Junior Research Fellow (sponsored by Council for Scientific and Industrial Research, Govt., of India) at National Institute of Virology (NIV), Pune, India.
2002-2003 Ph.D student at Medizinische Hochschule Hannover, Hannover.Germany.
2003-2007 Ph.D at Institute of Neurophysiology, University of Cologne. Germany.

Merits:

1. University 2nd rank in Bachelor of Science in Biochemistry, 1998.
2. Qualified "All India combined entrance exam" for admission into Master of Science in Biotechnology with fellowship from Department of Biotechnology, Govt. of India. 1998.
3. Qualified GATE (Graduate Aptitude Test in Engineering) conducted by Indian Institute of Technology, Govt.of India in 2000.
4. Awarded combined Junior Research Fellowship-cum-Lectureship by Council for Scientific and industrial Research (CSIR), Govt. of India and University Grants Commission (UGC), in 2000.
5. Awarded Junior Research Fellowship by Indian Council of Medical Research, India in 2001.
6. Cleared TOEFL (CAT) (score:253/300) 2001.

Cologne. 01.02.2007 (Michael Xavier Doss.J)

LEBENSLAUF

Name : Michael Xavier Doss.J

Addresse : Simmerer Strasse 27,
50935 Köln.
Deutschland.

Heimataddresse : 3/603 Bagath Singh Road,
Paramakudi-623707.
Tamil Nadu.Indien.
Email: xavi7677@yahoo.com

Geburtsdatum : 7. Juni 1978.

Staatsangehörigkeit : Indisch

Schulausbildung

1983-1988	Grundschule	Paramakudi, Indien
1988-1995	Gymnasium und Abitur	Paramakudi, Indien

Universität Studium

1995-1998	Bachelor of Science in Biochemie	Madurai Kamaraj Universität, Indien
1998-2000	Diplomarbeit in Biotechnologie	Calicut Universität, Indien.
2000-2001	Vorbereitungskurs für Doktoranden	Jawaharlal Nehru Universität, Indien.

Forschung

2001-2002 Forschungsstipendiat (gefördert von dem staatlichen Rat der wissenschaftlichen und industrieellen Forschung (CSIR) am Nationalen Institut für Virologie (NIV) in Pune, Indien.
2002-2003 Doktorand an der Medizinischen Hochschule in Hannover, Deutschland.
2003-2007 Doktorand am Institut für Neurophysiologie, Universität Köln, Deutschland.

Leistungen, Qualifikationen

1. 2. Platz beim Abschluß als Bachelor of Science in Biochemie an der Madurai Kamaraj Universität in Indien, 1998.
2. Qualifizierter staatlicher Aufnahmetest für das Studium als Stipendiat an ausgewählten Universitäten für Biotechnolgie in Indien, 1998
3. Qualifizierter Abschluß des staatlichen, akademischen Eignungstest (GATE) für das Ingenieurwesen, Indien 2000.
4. Staatliche Auszeichnung als Forschungsstipendiat mit Lehrerlaubnis durch den Rat der wissenschaftlichen und industriellen Forschung (CSIR) und der Universitäts Antrags Kommission (UGC), Indien 2000.
5. Staatliche Auszeichnung als Forschungsstipendiat durch den indischen Rat der medizinischen Forschung (ICMR), Indien 2001.
6. TOEFL Test (Ergebnis 253 von 300 Punkten), 2001.

Köln, 01.02.2007. Unterschrift
