CONTRIBUTIONS TO THE ASYMMETRIC CATALYSIS OF C-C COUPLINGS, AND TO THE CHEMICAL INDUCTION OF CARDIOMYOGENESIS FROM EMBRYONIC STEM CELLS

Inaugural Dissertation

zur Erlangung des Doktorgrades

der Mathematisch-Naturwissenschaftlichen Fakultät

der Universität zu Köln

vorgelegt von

Diplom-Chemikerin Bianca Seelig

aus Hilden

Köln 2009
Gutachter:

Pror. Dr. A. Berkessel
Prof. Dr. H.-G. Schmalz

Tag der mündlichen Prüfung:
06. Juli 2009
“Organic chemistry just now is enough to drive one mad.”

F. Wöhler, in a letter to his mentor J. J. Berzelius
Acknowledgments

Research work reported in this thesis was carried out from March 2006 until May 2009 at the Institute for Organic Chemistry of the University of Cologne under the supervision of Prof. Dr. Albrecht Berkessel. Additionally, a part of the research was done at the Graduate School of Pharmaceutical Sciences of the University of Tokyo, Japan, during October 2008 - February 2009, in the research group of Prof. Dr. Masakatsu Shibasaki.

First of all, I would like to acknowledge Prof. Dr. Albrecht Berkessel for providing me with those challenging and rewarding thesis projects. His constant help, critical advices and active encouragement were very important for the good outcome of this work.

Shibasaki-sensei deserves my sincerest gratitude for giving me the opportunity to work under his guidance at the tohôdai. どうもありがとうございます。

I would like to thank Prof. Dr. Hans Günther Schmalz for reviewing the thesis.

I would also like to mention the people who have been collaborating on the projects described in this thesis: Prof. Dr. J. Hescheler, Prof. Dr. A. Sachinidis and Dr. Silke Schwengberg as part of the stem cell project and the people at the Shibasaki group, especially Mastunaga-sensei and Morimoto-san, contributed in great extent to the success of this work.

I am very grateful to all my colleagues for providing a wonderful working atmosphere, for their help, patience and support. A standing ovation is to Ilona Jurkiewicz for being much more then the best lab mate one can imagine. I am thankful to my practical students, particularly for Jan Krämer, for sharing some of my experimental work. Thanks are also due to all of my Japanese colleagues, for the wonderful time in Japan.

For the critical reading of this work, I would like to thank Dr. Burkhard Koch, Dr. Nicolas Leconte, Angela Heinsch, Ilona Jurkiewicz, Eva Leitterstorf, David Müller, Mei Ching Ong and Dr. Silke Schwengberg.

My special thanks are to all the employees of the Institute for Organic Chemistry: Sarwar Aziz (HPLC), Dr. Nils Schlöer (NMR), Christoph Schmitz (GCMS), Dr. Johann Lex and Dr. Jörg Neudörfl (X-ray), Michael Neihs and Dr. Mathias Schäfer (MS). I also want to thank Susanne Geuer and Dr. Wolfgang Klug for their help in organisational
problems and Dietmar Rutsch and the members of the workshop, particularly Herbert Hartmann and Peter Küpper for their kind help with technical problems.

A big hug goes to all my dear friends for being there to remind me of the more important aspects of life.

I am grateful for my parents for giving me the freedom to find my own interests and goals and for their support and tolerance.

B., thank you for your encouragement, your support, and for always being there when I needed you.

1 Summary

This thesis deals with

- the investigation of chemically induced cardiomyogenesis of mouse ES cells,
- a simplified procedure for the synthesis of Takemoto’s catalyst,
- the development of the first Lewis acid catalysed asymmetric aza-BH reaction.

1.1 Chemically Induced Cardiomyogenesis of mES Cells

Cardiomyocytes are used as donor cells in cell replacement therapies to treat serious heart damage. Despite the significant demand for heart cells, there exists up to now no efficient method for the production of these donor cells. The most promising approach so far is the in vitro cardiomyogenesis from embryonic stem (ES) cells induced by small molecules. However, with this method, only a small ratio of stem cells evolve into cardiomyocytes. The design of new and highly selective small molecules is therefore of great interest.¹

1.1.1 Substance Screening

For the identification of a cardiomyogenesis inducing substance, a rational drug design (RDD) was performed with a preliminary diversity orientated screening (DOS) focused on the synthesis and screening of (thio)urea and cinchona alkaloid based libraries. Derivatives of these (thio)ureas and cinchona alkaloids are known to exhibit bioactivities correlated to decreased proliferation rates of cancer cells² or cardiac action potential,³ respectively.

A transgenic murine ES cell lineage, expressing enhanced green fluorescence protein (EGFP) under the control of the heart specific promoter α-myosine heavy chain (pα-MHC), was used to investigate the effects of the test substrates on cardiomyogenesis.

Diversity Orientated Screening (DOS). For a preliminary DOS, two substance libraries I and II containing (thio)urea (I, 19 compounds) or cinchona-alkaloid (II, 20 compounds) derivatives with extensively modified substitution patterns were synthesised and tested for their cardiomyogenesis inducing efficiency.

Among the substrates tested, especially compounds I-6, I-15 and II-16 induced an increase of 80 %, 50 % or 60 %, respectively, of the EGFP fluorescence which correlates with a positive cardiomyogenic effect (Scheme 1-1, p. 2).
I-6         I-15     II-16

Scheme 1-1 Influence of the compounds I-6, I-15 and II-16 on the expression of EGFP. Both a significant increase and decrease of values, compared to controls, represent an effect on the generation of cardiac cells.

Rational Drug Design (RDD). On the basis of the three lead structures (I-6, I-15, II-16), a focused (thio)urea (III, 8 compounds) and a focused cinchona-alkaloid based library (IV, 9 compounds) were created, tested for their cardiomyogenic activity, and analysed in a RDD approach.

The results obtained with the (thio)urea based library did not provide a sufficiently solid and reliable basis for a meaningful structure-activity relationship (in this case of small molecule induced cardiomyogenesis).

In contrast, RDD analysis of the physiological screening of the cinchona alkaloid based library IV showed that especially variations on the alkoxy group (IV-5) and the quarternary ammonium moiety (IV-8) lead to an increased formation of cardiomyocytes (Scheme 1-2).

Scheme 1-2 Influence of the variations on the alkoxy and quarternary ammonium substituents (compounds IV-5 and IV-8) on the expression of EGFP. Both a significant increase and decrease of values, compared to controls, represent an effect on generation of cardiac cells.
Based on these positively tested substances (compounds IV-5 and IV-8), a new quinidine based substance library V (8, compounds) was developed and screened for its cardiomyogenesis inducing effectivity. This library contains substances which differ either in the alkoxy group attached to the quinidine moiety, or in the quinuclidine N-substituent compared to the lead structures IV-5 and IV-8. However, these structural modifications did not improve the cardiomyogenesis inducing effect of the lead structures.

Conclusion. The substance screenings led to the identification of cardiomyogenesis inducing compounds with good (IV-5) to very good activities (II-16, IV-8) determined by a 50 to 80 % increase of the EGFP fluorescence compared to untreated cells.

1.1.2 Identification of Signalling Cascades Involved in Cardiomyogenesis

Verapamil rac-6, a cardiomyogenesis inducing agent found in previous studies, and the most active compound identified in the substance screening II-16 were used for the identification of signalling cascades involved in the cardiomyogenesis by a time-dependent screening approach. In this method, an increased cardiomyogenesis indicates interaction of the compound tested with a target expressed at a certain point in time during the application time-frame of the test substrate.

Since both substrates exhibited different cardiomyogenesis inducing profiles in each test series, the cardiomyogenesis inducing effect of the tested substrates appeared to rely on an interaction of the tested substances with several target proteins expressed at different points of time. In this case, time-dependent correlations between cardiomyogenesis and concentrations of the substrates are not suitable to limit the number of potential targets associated to the various developmental stages.

1.2 A Simplified Synthesis of Takemoto’s Catalyst

A significant number of C-C couplings can be catalysed enantioselectively by Takemoto’s bifunctional amino thiourea derivative 51. The original synthesis of the amino
thiourea catalyst 51 consists in the facile addition of isothiocyanate 43 to \( N,N \)-dimethyl-trans-1,2-diaminocyclohexane 11. The preparation of the \( N,N \)-dimethyl-trans-1,2-diaminocyclohexane building block 52 is a laborious four step procedure (Scheme 1-4).\(^6\)\(^7\)

![Scheme 1-4 Synthesis of the amino thiourea 51 developed by Takemoto.](image)

An improved synthesis of Takemoto’s catalyst 51 was realised consisting of only two steps: The thiourea moiety was obtained by condensation of 3,5-bistrifluoromethyl-aniline 68 with phenyl chlorothioformate 71 and subsequent reaction with trans-1,2-diaminocyclohexane 11, according to a modified reaction protocol of Nagasawa.\(^8\)

Subsequent reductive dimethylation using formaldehyd / zinc afforded Takemoto’s catalyst in an overall yield of 36 % (Scheme 1-5).

![Scheme 1-5 Improved synthesis of Takemoto’s catalyst 51.](image)

1.3 **La-linked BINOL Catalysed Asymmetric aza-BH reaction**

The asymmetric aza-Baylis-Hillman (aza-BH) reaction of achiral imines with acrylates provides a direct access to chiral \( \beta \)-amino acid esters, which have gained considerable interest due to their important biological properties, their occurrence in natural products, and as potential precursors for \( \beta \)-lactams.\(^9\)

In this work, the first aza-Baylis-Hillman reaction catalysed by a chiral Lewis acidic complex was developed. Diphenylphosphinoyl- (dpp-) protected imines were employed as electrophiles, due to the ease of removal of this activating and protecting group.

In an initial ligand screening with La(O\(i\)Pr\(_3\)) and various \((R)\)-BINOL-based ligands (Scheme 1-6, p. 5), high enantioselectivity was achieved with linked-\((R,R)\)-BINOL 97. Since raising the ligand to metal ration for \((R)\)-BINOL 101 from 1:1 to 2:1 showed no beneficial effect, the increase in enantioselectivity for linked-\((R,R)\)-BINOL 97 complex was
discussed as effect of its higher stability compared to the La-(R)-BINOL complex. The introduction of sterically more demanding substituents in the (R)-BINOL 3,3’ position lead to catalysts with low reactivity and enantioselectivity.

Scheme 1-6 Screening of (R)-BINOL-based ligands.

The La-linked-(R,R)-BINOL complex is well known for its dual reactivity as Lewis acid and Brønsted base. However, increasing the basicity of the catalyst by deprotonation with KHMDS, NaHMDS or n-BuLi did not result in higher yields or enantioselectivities relative to the non-metallated species.

A variation of the catalyst’s Lewis-acidity by complexation of linked-(R,R)-BINOL 97 with various M(OiPr)ₓ, identified Ln-complexes as the most efficient catalysts, whereas the more Lewis-acidic Ti-complex as well as the more Lewis basic Sr-complex led to decreased yields and enantioselectivities.

An extensive screening of the reaction parameters was performed. The optimised conditions are shown in Scheme 1-7.

Scheme 1-7 Optimised reaction conditions for the aza-BH reaction catalysed by La-linked-BINOL

In a substrate screening, among the acrylates tested, the highest yields were achieved with 2-naphthyl acrylate 99d (up to 67 %), while methyl acrylate 99a led to the highest enantioselectivities (up to 90 % ee). Comparison of dpp-protected benzaldimine 98a with its para-Cl-substituted analogue 98b revealed in most cases higher enantioselectivities at virtually unchanged yields for the para-Cl-substituted and dpp-protected benzaldimine 98b. Aliphatic imines were also tested, but only traces of the corresponding aza-BH adducts were detected.
Hydrolytic deprotection of the aza-Baylis-Hillman products 100 provided single step access to the corresponding $\beta$-amino acids 106 in up to 75 % yield (Scheme 1-8).

Scheme 1-8 Single step conversion of aza-BH adducts 100 to $\beta$-amino acids 106.

Conclusions. It was shown for the first time that the aza-Baylis-Hillman reaction can be catalyzed enantioselectively by a chiral Lewis acidic metal complex. Using the La-linked-(R,R)-BINOL complex as catalyst and dpp-protected imines as substrates the corresponding aza-BH adducts could be obtained in up to 68 % yield and up to 90 % ee. Hydrolytic deprotection of the highly enantio-enriched aza-Baylis-Hillman products thus obtained grants access to $\alpha$-methylene-$\beta$-aminoacids in a simple one pot-procedure.
2 Introduction

In modern sciences, interdisciplinary fields become more and more important. For example, organic chemistry and biology are linked by the building blocks of life. Chemically, such building blocks of life are small organic molecules (i.e. amino acids, sugars and nucleic bases) or polymers (i.e. proteins, nucleic acids, carbohydrates). Biologically, the building blocks of life are cells (Scheme 2-1).

Scheme 2-1: Building block of life as interdisciplinary field of organic chemistry and biology and their relations to applied chemistry.

Cellular biology, studied since the 1800s, is the basis of current stem cell research. The advent of the microscope provided scientists a first look at human cells. At this time cells were identified as the building blocks of life, capable of reproducing and differentiating into all the cell types that make up the living body.

Although the history of stem cell research started in the early 1900s with the discovery that the various types of blood cells all came from a particular ‘stem cell’, the potential of these stem cells has been discovered in the late 1960s: McCulloch and Till detected self-renewing cells in mouse bone marrow\textsuperscript{10} and Altman as well as Das showed that adult neurogenesis was accompanied by stem cell activity in the brain.\textsuperscript{11}

Stem cell research has basically focused on bone marrow transplants. Since 1950, theses transplants have been used in patients additionally treated with radiation and
chemotherapy. However, first the pioneering discovery by Dausset in 1958, which identified the first human histocompatibility antigens, enabled the establishment of this stem cell therapy.

Developments in biotechnology in the 1980s and 1990s afforded techniques for targeting and altering genetic material as well as methods for growing human cells in the laboratory. These advances opened the doors for stem cell research.

In 1998, Thompson isolated cells from the inner cell mass of early embryos, and developed the first embryonic stem cell lines. The blastocysts used for human stem cell research typically originate from in vitro fertilization procedures.

These discoveries stimulated further research. The growing interest in stem cell research is evident from the exponential increase of publications in this research area. The possibilities for stem cell research are indeed endless, but yet unpredictable. If scientists can master the biochemistry behind stem cell development, stem cell technology could be used, e.g. to produce replaceable tissues or organs.

A contribution to the stem cell development is the subject of the present work. In the first part of this thesis, the in vitro development of cardiomyocytes from ES cells induced by small molecules is described.

Organic compounds such as pharmaceuticals, agrochemicals, flavors and fragrances play an important role in modern life. These compounds possess biological activity which arises from the interaction of the organic compound with a biological target. These biomolecules are single enantiomers of chiral compounds since they are constructed from chiral building blocks such as amino acids or carbohydrates, which are present in nature as a single enantiomer.

Besides ex chiral pool syntheses (Scheme 2-2 (a)), there are two general methods for obtaining enantiomerically enriched compounds: (Scheme 2-2 (b)) they may be synthesised in racemic form and resolved into their optical antipodes, or (Scheme 2-2 (c)) the synthesis may be directly performed in an enantioselective manner.

(b) An example for the separation of enantiomers by chemical resolution based on the selective crystallisation of one enantiomer by diastereomeric salt formation. Although this method is not generally applicable, it is still quite popular for the large scale preparation of enantiomerically pure acids or amines. Other approaches of resolution involve the formation of covalent bonds between the racemic substrate and an enantiomerically pure compound. The resulting diastereomeric compounds can be separated by chromatographic technics and the desired enantiomer can be regenerated from the
appropriate diastereomer by chemical transformations. However, these methods yield only up to 50% of the desired enantiomer.

(c) For asymmetric syntheses, i.e. the generation of enantio-enriched compounds from achiral precursors, chiral auxiliaries, chiral reagents or chiral catalysts, all in enantio-pure form, can be employed. There are prominent auxiliar-based synthesis, e.g. Ender’s SAMP/RAMP\textsuperscript{16} or Schöllkopf’s bislactim ether\textsuperscript{17} syntheses. However, the covalent binding to and cleaving from the substrate makes these procedures less efficient. Chiral enantio-pure reagents, e.g. BINAL-H,\textsuperscript{18} must be employed in stoichiometric quantities, this likewise decreases the efficiency of the synthesis. Hence, enantioselective catalyses with small amounts of “chiral information” are the most efficient procedures to obtain enantiopure chiral compounds. There are three different kinds of chiral catalysts employed in asymmetric synthesis, biocatalysts,\textsuperscript{19} metal ligand complexes derived from chiral ligands,\textsuperscript{20} and chiral organocatalysts.\textsuperscript{21} Enzymes as biocatalysts are very selective and efficient, but often tolerate only small temperature ranges, few solvents and a narrow range of substrates. Metal complex catalysts are widely applied in organic chemistry, although the ligands and metals are often quite expensive. Catalysis by small organic molecules, e.g. proline, complements enantioselective synthesis, as such catalysts are often cheap, easy to modify and less toxic.

\begin{center}
\textbf{Scheme 2-2} Three methods to obtain chiral, enantio-enriched compounds.
\end{center}
Although impressive results were achieved in the field of asymmetric catalysis in the last decades, there is still the need for the development of highly selective and effective catalytic systems.

A contribution to this is the subject of the present work. In the second and third part of this thesis, an improved two step synthesis of a prominent organocatalyst as well as the development of a new catalytic system for an established C-C coupling is described.
Chemically Induced Cardiomyogenesis of mES Cells

3.1 Background

Cardiomyopathy results from the loss of functional heart muscle cells, impairing the ability of the heart to maintain adequate blood circulation. As adult differentiated cardiomyocytes lack prominent regenerative capacity, heart transplantation remains the only effective causal treatment. An increasing number of patients suffer from severe heart failure, and the shortage of available donor organs emphasise the demand for alternative therapy methods, such as cellular cardiomyoplasty. In this context, several animal studies demonstrated a successful engraftment of cardiac myocytes into the adult heart.\textsuperscript{22,23} However, the limiting factor for a general application of cell therapy for the treatment of cardiovascular diseases still is the insufficient number of donor cells. Embryonic stem (ES) cells isolated from the inner cell mass of early blastocyst-stage embryos are pluripotent. They are capable of differentiating \textit{in vitro} into any somatic cell type, including cardiomyocytes, haematopoietic progenitors, skeletal myocytes, smooth muscle cells, adipocytes, chondrocytes, endothelial cells, neurons and glia and pancreatic islet cells.\textsuperscript{15} When cultured in the presence of leukaemia inhibitory factor (LIF), ES cells remain undifferentiated and can be propagated indefinitely. Upon withdrawal of LIF, ES cells spontaneously and irreversibly differentiate into multicellular aggregates, so-called embryoid bodies (EBs). These aggregates resemble early post-implantation embryos and contain derivatives of all three germ layers.\textsuperscript{24}

So far, the \textit{in vitro} differentiation of ES cells into cardiomyocytes offers a new approach for cellular therapy of degenerative heart diseases. Therefore, the development of new approaches allowing a direct differentiation of ES cells into cardiomyocytes is of growing interest.\textsuperscript{25}

The differentiation programs of ES cells can be shifted toward cardiomyogenic or neuronal differentiation by treatment with small molecules, such as retinoic acid 1 or dimethyl sulfoxide (DMSO) 2 (Scheme 3-1), at specific stages of differentiation.\textsuperscript{26,27}

\begin{center}
\textbf{Scheme 3-1:} Retinoic acid 1 (left) and DMSO 2 (right).
\end{center}
However, this approach is not very efficient, and normally requires selection to enrich specific cell lineages. Several small molecules have recently been found to control the differentiation of ES cell into a specific cell lineage as well as to affect the self renewal of ES cells:

**Ascorbic acid.** In 2003 Takashi et al.\(^28\) screened 880 compounds of the *FDA2000 Drug Library*, which were approved for human use, for their potential to induce cardiac differentiation of mouse ES cells in a monolayer culture. They used CGR8 mouse ES cells stably transfected with the cardiac muscle-specific \(\alpha\)-MHC promoter driven EGFP as a reporter. They found that upon treatment with ascorbic acid 3 (vitamin C, Scheme 3-2, p. 14) increased cardiac differentiation of ES cells in a dose-dependent manner. It can be assumed that this effect of ascorbic acid is independent of its antioxidative property\(^29\), because antioxidants normally inhibit ES cell differentiation into cardiac myocytes, whereas ROS (reactive oxygen species) like \(\text{H}_2\text{O}_2\) or radical-generating menadione enhance cardiogenesis\(^30\). Other antioxidative agents such as \(N\)-acetylcystein, Tiron (brenzocatechine-3,5-disulfonic acid disodiumsalt) or vitamin E also do not mimic the effect of ascorbic acid on the cardiac differentiation. In addition, there was no significant effect of vitamin C 3 on the cardiomyogenesis via embryoid body formation. This suggests that ascorbic acid induces permissive changes that occur during the formation of embryoid bodies, rather than induction of autonomous commitment of ES cells to cardiac myocytes.

**5-Aza-2’-deoxycytidine.** Based on the results of Fukuda et al.\(^31\), who ascertained an increased cardiomyogenesis of mesenchymal stem cells by adding the DNA-demethylating agent 5-aza-2’-deoxycytidine 4 (Scheme 3-2, p. 14), Xu et al.\(^32\) tested the effect of this compound on the differentiation of human ES cells into cardiomyocytes via embryoid body formation. Using immunostaining and real-time PCR they observed an increase of cardiomyocyte formation by treating the human ES cells with 5-aza-2’-deoxycytidine 4. Interestingly, DMSO and retinoic acid, which have been shown to induce cardiomyocyte differentiation in mouse ES cells (see above), did not enhance human ES cell cardiomyocyte differentiation.

**Cardiogenol C.** Schultz et al.\(^33\) screened a 100.000 compound library of so called privileged heterocycles\(^34\) using a stable engineered mouse embryonic carcinoma cell line P19 expressing luciferase under the control of the ANF promoter under monolayer
conditions. Like ES cells, P19 cells are pluripotent and are capable of differentiating into cardiac cells under specific culture conditions.\textsuperscript{35} They identified 80 compounds that increased luciferase activity. In addition, 35 compounds induced a parallel expression of sarcomeric $\alpha$-MHC, a cardiac specific protein. In particular, these compounds share significant structure similarities possessing a 2-hydroxylamino substitution at the C-4 position and large, hydrophobic groups at the C-2 position. To confirm that these compounds are general cardiomyogenesis inducing agents, they analysed their effects on undifferentiated R1 mouse ES cells also in a monolayer culture. They detected more than 90\% positive cardiomyocyte formation of ES cells treated with Cardiogenol C\textsuperscript{5} (Scheme 3-2, p.14). Furthermore, they observed that compound treatment slowed down cellular proliferation with no significant cell death, indicating that this process is not simply a selection for cardiac precursor cells with the death of cells in other lineages.

**Verapamil, Ryanodine, Cyclosporin.** Sachinidis et al.\textsuperscript{4} investigated the effects of 33 small molecules interfering with several signalling cascades on cardiomyogenesis. They used a transgenic ES cell lines expressing enhanced green fluorescent protein (EGFP) under the control of the $\alpha$-myosin heavy chain promoter ($p_{\alpha}$MHC). In this screening, especially the L-type Ca\textsuperscript{2+} channel blocker Verapamil\textsuperscript{6} as well as Ryanodine\textsuperscript{7}, an inhibitor of the protein phosphatase 2B, and Cyclosporin A\textsuperscript{8}, an Calcineurin inhibitor (Scheme 3-2, p. 14), exerted the most striking pro-cardiomyogenic effect. Treatment of the EBs with Verapamil\textsuperscript{6} caused a pronounced 94\% increase and treatment with Ryanodine\textsuperscript{7} resulted in a significant 75\% increase of the EGFP fluorescence compared to untreated cells. Ryanodine\textsuperscript{7} is a natural compound acting through binding to the Ryanodine receptor (RyR), the Ca\textsuperscript{2+} channel of the sarcoplasmatic reticulum (SR), resulting in the release of Ca\textsuperscript{2+} into the sarcoplasm. Depending on the cell type and concentration, Ryanodine\textsuperscript{7} induces an inhibition or activation of the release of Ca\textsuperscript{2+} from SR.\textsuperscript{36} Verapamil\textsuperscript{6} is an antagonist of the plasma membrane L-type Ca\textsuperscript{2+} channel thereby inhibiting the influx of extracellular Ca\textsuperscript{2+} into the cytosol.\textsuperscript{37} Furthermore, Sachinidis et al. observed that spontaneous contractions of ES cell derived cardiomyocytes were totally inhibited when Verapamil\textsuperscript{6} was present at late stages of cardiac differentiation. From these results, Sachinidis et al. concluded that cytosolic Ca\textsuperscript{2+} is involved in the differentiation of cardiomyocytes from ES cells and that [Ca\textsuperscript{2+}]$_i$ lowering agents promote cardiomyogenesis even if the physiological activity of beating is inhibited.
Exposure of EBs to Cyclosporin A 8 caused an increase of the EGFP fluorescence up to 140 %. Cyclosporin A 8 is an amino acid cyclic peptide used as immunosuppressant compound. Complexes of Cyclosporin A 8 with the immunophilin Cyclophilin A within the cell inhibit the Ca\(^{2+}\)- and calmodulin-dependent protein phosphatase 2B (Calcineurin). Furthermore there is an accumulating evidence that Calcineurin is also involved in the regulation of other cellular processes such as embryonic development and cancer, as well as cardiac valve formation and cardiac hypertrophy.\(^{38}\)

![Chemical structures](image)

### 3.2 Concept

#### 3.2.1 Forward Chemical Genetics Approach

The *in vitro* differentiation of ES cells into cardiomyocytes offers a new approach for cellular therapy of degenerative heart diseases. For a direct differentiation of ES cells into cardiomyocytes experimental methods are required allowing rapid and “easy to handle” parallel testing of small molecules which may influence the differentiation of ES cells towards cardiomyocytes. For this aim, a transgenic ES cell lineage is used, expressing enhanced green fluorescent protein (EGFP) under the control of the heart specific promoter \(\alpha–\)myosine heavy chain (\(\rho\alpha\)-MHC) to test selected substances for their cardiomyogenesis inducing activity (Scheme 3-3, p. 15).\(^{39,40}\)
Scheme 3-3 Forward chemical genetics approach. After culturing of transgenic ES cells in multi-well plates, a library of small molecules can be screened by addition of one single compound per well. After differentiation, small molecules can be identified participating in the generation of the desired phenotype. Further modifications based on the structure of these active test substrates should lead to an enhanced differentiation potential of the tested compounds.

In general, two strategies exist for the identification of cardiomyogenesis stimulating substances: structure based drug design (SBDD), or rational drug design (RDD).\textsuperscript{41,42,43} The SBDD involves the search for a small molecule that perfectly fits in the binding pocket of a target protein, and thus influences the signalling pathway. An application of this method requires knowledge about the signalling pathways, the proteins involved and their structures.

The RDD describes the relationship between chemical structures and their biological effects. For a successful correlation all tested compounds must bind to the same target. To fulfil this requirement, the test substrates must have very similar chemical structures. To find a capable lead structure for the RDD, a foregoing diversity orientated screening (DOS) is performed. Within this screening, substances are tested which cover a broad structural spectrum with fixed core structures.
As the structures of the proteins involved in the signalling pathways - which are assumed to promote cardiomyogenesis of ES cells - are mostly unknown, the requirements for a SBDD approach are not fulfilled. Therefore a RDD with a preliminary DOS was performed focused on the synthesis and screening of (thio)urea and cinchona-alkaloid based compound libraries.

### 3.2.2 Selection of Substrates

Stem cells and cancer cells share the similarity that both cell types exhibit high proliferation rates. According to the cancer stem cell theory, drugs which induce differentiation of stem cells thereby also decrease their proliferation rates. If the same applies for cancer cells, drugs for cell differentiation could be used for anti-cancer therapies and vice versa. The prominent anti cancer drug Nexavar® (Sorafenib) harbours a thiourea moiety (Scheme 3-4).\(^2\) Therefore, the selection of substances has been focused first on (thio)urea derivatives.

![Scheme 3-4 Chemical structure of the prominent anti cancer drug Nexavar®.](image)

A second selection of substances has concentrated on ammonium salts derived from cinchona alkaloids, as they are well known for their phase transfer abilities\(^44\) which should promote membrane permeation by drugs. Furthermore, quinidine is a pharmaceutical agent that acts as a class I antiarrhythmic agent in the heart. The effect of quinidine on the ion channels is to prolong the cardiac action potential and thereby prolonging the QT interval on the surface electrocardiogram (ECG).\(^3\)

### 3.3 Results and Discussion

#### 3.3.1 Substance Screening

For the identification of a cardiomyogenesis stimulating substance, a rational drug design with a preliminary DOS focused on the synthesis and screening of (thio)urea and cinchona-alkaloid based compound libraries was performed.
Differentiation Protocol – for DOS, RDD. A transgenic murine ES cell lineage expressing enhanced green fluorescent protein (EGFP) under control of α-myosine heavy chain (α-MHC) promoter (pα-MHC-EGFP) was used to investigate the effects of (thio)urea and cinchona-alkaloid derivatives on cardiomyogenesis. To start differentiation, ES cells were cultured in suspension for 12 h to form EBs. About fifty EBs were transferred to each well of bacterial 6-well plates and the test compounds were added. On day 7, fresh medium and fresh test compounds were added. On day 14, EBs on each plate were counted, lysed and the EGFP fluorescence in the lysates was measured at an excitation wavelength of 476 nm and an emission wavelength of 508 nm.

Diversity Orientated Screening (DOS). For a first DOS, two substance libraries I and II containing (thio)urea (I) or cinchona-alkaloid (II) derivatives with extensively modified substitution patterns (Scheme 3-5 and Scheme 3-6, p. 18-19) were synthesised and tested for their cardiomyogenesis inducing efficiency.
Scheme 3-5 Structures contained in the (thio)urea-based library I.
The cardiomyogenic effect of the substances is expressed as percent of the EGFP fluorescence of the vehicle treated cells (100%). An increased production of cardiomyocytes gives percent of control values higher than 100 %, a decreased production of cardiomyocytes lower than 100 %.

Scheme 3-6 Structures contained in the cinchona-alkaloid-based library II.
Among the (thio)urea derivatives (library I) tested, especially the bis-ureas I-6 and I-15 induced an increase of 80 % or 50 %, respectively, of the EGFP fluorescence which correlates with a positive cardiomyogenic effect. In the cinchona-alkaloid based library II the best result could be obtained with the quinidine based salt II-16 which induced a 60 % increase (Scheme 3-7).

Scheme 3-7 Influence of the compounds I-6, I-15 and II-16 on the expression of EGFP, normalised to the number of EBs. Values from four independent experiments (mean ± SD, n=4), each performed in triplicate, are displayed as percent of control values (=100 %, only vehicle, without test substrate). Both a significant increase and decrease of values, compared to controls, represent an effect on the generation of cardiac cells.
**Rational Drug Design (RDD).** On the basis of the three lead structures (I-6, I-15, II-16) found in the foregoing diversity orientated screening, a focused (thio)urea (III, Scheme 3-8) and a focused cinchona-alkaloid based library (IV, Scheme 3-9) were created. These libraries were tested for their cardiomyogenic activity and analysed in a rational drug design. As mentioned before, a meaningful RDD requires binding to the same target protein. Therefore, analogues were synthesised which differ only slightly compared to the starting compounds, as smaller structural differences can be assumed to lead to a higher probability of binding to the same target protein.

The substrates III-1, III-3 and III-5 (Scheme 3-8) are based on the lead structure I-6. They differ from this lead compound in the thiourea moiety (III-1) or in the aromatic 3,5-substituents (III-3, III-5). Test compounds III-2, III-4 and III-7 were evolved from the lead structure I-15. Substrate III-2 harbours a thiourea function instead of the urea moiety and the test compounds III-4 and III-7 exhibit additional aromatic 3,5-substituents. Variation of the chiral diamino backbone led to the test compounds III-6 and III-8.

![Scheme 3-8](image)

Scheme 3-8 Structures contained in the focused (thio)urea-based library III. Differences to the lead structures I-6 resp. I-15 are coloured in red.

The substrates in library IV (Scheme 3-9) differ from the lead structure II-16 in the methylated hydroxyfunction (IV-1), the hydrogenated double bond (IV-2), the inversion...
of the stereocenters at C8 and C9 (IV-9), a variation in the alkoxy group (IV-4 and IV-5) or in the quaternary ammonium moiety (IV-3, IV-6, IV-7, IV-8).

Scheme 3-9 Structures contained in the focused cinchona alkaloid-based library IV. Differences to the lead structure II-16 are coloured in red.

The cardiomyogenesis inducing effect of the lead structures I-6, I-15, identified in the DOS, could not be reproduced in the RDD screening, despite the fact that the same screening method (see differentiation protocol) was used (Scheme 3-10, p. 23). Consequently, (thio)ureas and their structural variations appear not to provide a sufficiently solid and reliable basis for a meaningful structure-activity relationship (in this case of small molecule-induced cardiomyogenesis).
Scheme 3-10 Influence of the compounds I-6 and I-15 on the expression of EGFP, normalised to the number of EBs. Values from four independent experiments (mean ± SD, n=4), each performed in triplicate, are displayed as percent of control values (=100 %, only vehicle, without test substrate). Both a significant increase and decrease of values, compared to controls, represent an effect on the generation of cardiac cells (left – results of the physiological screening of compound I-6; right – results of the physiological screening of compound I-15).

A possible explanation for these results might be that the thio(urea)-substrate binding is not specific, but rather depends on medium parameters, such as pH value or temperature, which are influenced by metabolism of the ES cells and therefore can hardly be controlled. Such small changes in the experimental environment would then lead to a significant influence of a possible (thio)urea induced cardiomyogenesis.

In contrast, in the quinidine based library IV, the positive effect of the lead structure II-16 on the generation of cardiac cells identified in the DOS could be reproduced in the RDD,
i.e. the shapes of the curves are very similar, both show maximal effect (in between 60 to 80 % increase) at a substrate concentration of $1 \cdot 10^{-5}$ M (Scheme 3-11).

**Scheme 3-11** Influence of the compound **II-16** on the expression of EGFP, normalised to the number of EBs. Values from four independent experiments (mean ± SD, n=4), each performed in triplicate, are displayed as percent of control values (=100 %, only vehicle, without test substrate). Both a significant increase and decrease of values, compared to controls, represent an effect on generation of cardiac cells (top – results of the physiological screening for the DOS; bottom – results of the physiological screening for the RDD).

RDD analysis of the physiological screening of the cinchona alkaloid based library **IV** shows that, compared to the lead structure **II-16**, the inversion of the C8 and C9 stereo-centers (**IV-9**), the hydrogenation of the double bond (**IV-2**) or the methylation of the hydroxyfunction (**IV-1**) result in the loss of cardiomyogenesis-inducing activity. In contrast, especially variations on the alkoxy group (**IV-5**) and the quarternary ammonium moiety (**IV-3,6,7,8**) lead to an increased formation of cardiomyocytes. The best hits could be obtained with the quinidine derivatives (**IV-5**) (up to 50 % increase) and (**IV-8**) (up to 70 % increase) (Scheme 3-12, p. 25).
Scheme 3-12 Influence of the variations on the alkoxy and quarternary ammonium substituents (compounds IV-5 and IV-8) on the expression of EGFP, normalised to the number of EBs. Values from four independent experiments (mean ± SD, n=4), each performed in triplicate, are displayed as percent of control values (=100 %, only vehicle, without test substrate). Both a significant increase and decrease of values, compared to controls, represent an effect on generation of cardiac cells.

Based on these positively tested substances (compounds IV-5 and IV-8), a new quinidine based substance library V was developed and screened for its cardiomyogenesis inducing effectivity. This library contains substances which differ either in the alkoxy group attached to the quinidine moiety (V-8), or in the quinuclidine N-substituent (V-1 - V-7) compared to the lead structures IV-5 and IV-8 (Scheme 3-13, p. 26)
Physiological screenings of the quinidine based library V identified compound V-4 as the most effective cardiomyogenesis inducing substance with a maximal 50% increase of the EGFP fluorescence at a concentration of $1 \times 10^{-6}$ M (Scheme 3-14). In summary, the structural modifications introduced by compounds V-1 – V-8 did not improve the cardiomyogenesis inducing effect of the original hit, i.e. compound II-16 (60-80% increase in cardiomyogenesis).

**Scheme 3-14** Influence of compound V-4 on the expression of EGFP, normalised to the number of EBs. Values from four independent experiments (mean ± SD, n=4), each performed in triplicate, are displayed as percent of control values (=100%, only vehicle, without test substrate). Both a significant increase and decrease of values, compared to controls, represent an effect on the generation of cardiac cells.
3.3.2 Identification of Signalling Cascades Involved in Cardiomyogenesis

The best hit of the substance screening II-16 and Verapamil 6, a cardiomyogenesis inducing agent found in previous studies, were used for the identification of signalling cascades involved in the cardiomyogenesis by the time-dependent screening approach. In contrast to previous screenings, in this approach, the test substrates were only applied for 2 instead of 14 days. An increased cardiomyogenesis, detected after 14 days, indicates interaction of the compound tested with a target expressed at a certain point in time during the application time-frame of the test substrate. Thus, time-dependent correlations between cardiomyogenesis and concentrations of the substrates are expected to limit the number of potential targets associated to the various developmental stages (Scheme 3-14).

**Scheme 3-15** Limitation of potential targets by a time-dependent screening.

**Differentiation Protocol - Time Dependent Screening.** In contrast to the differentiation protocol described above (p. 16), in time-dependent studies, the test substrates are applied at different intervals (day 1-3, 3-5, 5-7, 7-9).
**Time Dependent Screening.** For the time-depending screening, the cinchona-alkaloid II-16 and (racemic) Verapamil rac-6 were used as test substrates (Scheme 3-16). Among all substances tested in the physiological screenings, these two led to the highest ratio of cardiomyocytes and may best contribute to the identification of the signalling pathways involved in cardiomyogenesis.

![Chemical structures](image)

**Scheme 3-16** Cinchona alkaloid II-16 (left), verapamil rac-6 (racemic mixture, right).

For each application time-frame (days 1-3, 3-5, 5-7 and 7-9) three different concentrations ($10^{-5}$ M, $10^{-6}$ M and $10^{-7}$ M) of the quinidine derivative II-16 and Verapamil rac-6 were tested in three identical test series. The cardiomyogenic effect of the substances is expressed as percent of the EGFP fluorescence of the vehicle treated cells (100%). An increased production of stem cells gives percent of control values higher then 100 %, a decreased production of stem cells lower than 100 %.

As shown in Scheme 3-17 (p. 29), both substrates exhibit different cardiomyogenesis inducing profiles in each test series. Based on these results, the cardiomyogenesis inducing effect of the test substrate II-16 and verapamil rac-6 appeared to rely on an interaction of the tested substances with several target proteins expressed at different points of time. In this case, time-dependent correlations between cardiomyogenesis and concentrations of the substrates are not suitable to limit the number of potential targets associated to the various developmental stages.
Scheme 3-17 Time-dependent effects of quinidine derivative II-16 (left) and Verapamil rac-6 (right) on the expression of EGFP, normalised to the number of EBs. Values of three independent test series for four application time frames, each performed in triplicate, are displayed as percent of control values (=100 %, only vehicle, without test substrate). Both a significant increase and decrease of values, compared to controls, represent an effect on generation of cardiac cells.

Conclusions. The substance screening led to the identification of cardiomyogenesis inducing compounds with good (IV-5, V-4) to very good activities (II-16, IV-8) determined by a 50 to 80 % increase of the EGFP fluorescence compared to untreated cells. Time-dependent screenings in which compounds were added at different developmental stages of the ES cell were of limited suitability for the identification of possible targets addressed by active reagents. Further insight on target binding might be achieved by the expression of isolated targets and their induction with test substances.
3.3.3 Synthesis of the Test Substrates

Substance Library I. The test substrates of the substance library I were synthesised by Dr. M. Brandenburg, Dr. F. Cleemann, Dr. S. Mukherjee, Dr. T. Müller, Dr. S. Schnippering and Dr. K. Roland.

Substance Library II. The test substrates of the substance library II were synthesised by Dr. M. Guixà and Dr. F. Schmidt.

Substance Library III. To generate the (thio)urea based library III the chiral diamino-backbones, consisting of (1S,2S,4S,5S)-2,5-diamino-bicyclo[2.2.1]heptane (DIANANE) 9, (1R,3S)-3-aminomethyl-3,5,5-trimethylcyclohexylamine (IPDA) 10 and (1R,2R)-1,2-diaminocyclohexane (DACH) 11, were synthesised first.

For the synthesis of DIANANE 9, norbornadiene 12 was first hydrated to form the corresponding diol 13 in 36 % yield. Oxidation of the hydroxy-functions led to the diketone 14 in 61 % yield. Reductive amination of the carbonyl-functions resulted in the benzyl protected diamine 15 in 97 % yield and deprotection of 15 afforded the desired DIANANE 9 in 98 % yield (Scheme 3-18).

Commercially available IPDA mix-10 is a mixture of the racemic cis- and trans-diastereomers in a 3 : 1 ratio. The optical resolution of IPDA mix-10 was performed via a diastereoselective salification with (R,R)-dibenzoyltartaric acid 16 (Scheme 3-19, p. 31).
The optical resolution of the commercially available racemic 1,2-diaminocyclohexane rac-11 was carried out via a diastereoselective salification using L-(+)-tartaric acid 18 (Scheme 3-20).

Addition of the chiral diamines (1S,2S,4S,5S)-DIANANE 9, (1R,3S)-IPDA 10 and (1R,2R)-DACH 11 to the iso(thio)cyanates, according to a general procedure (Scheme 3-21), yields the corresponding (thio)urea derivatives of the substance library III.

The yields of these syntheses are given in Scheme 3-22, p. 32.
Substance Library IV. For the preparation of the cinchona-alkaloid based library IV, quinidine 19 was first transformed to the derivatives 20, 21 and 22.

Scheme 3-22 Compounds contained in the (thio)urea based library III.

1 Compound III-1 was synthesised by Dr. M. Brandenburg.
Methylation of the hydroxy function of quinidine 19 with methyl iodide 23 resulted in the quinidine derivative 20 in 90 % yield (Scheme 3-23).

\[
\begin{align*}
\text{Scheme 3-23 Synthesis of 9-O-methylquinidine 20.}
\end{align*}
\]

Hydrogenation of the aliphatic double bond of quinidine 19 with Pd/C led to the quinidine derivative 21 in 94 % yield (Scheme 3-24).

\[
\begin{align*}
\text{Scheme 3-24 Synthesis of 10,11-dihydroquinidine 21.}
\end{align*}
\]

Quinidine derivative 22 was obtained in 61 % yield by cleavage of the aromatic ether function of quinidine 19 with BBr₃ (Scheme 3-25).

\[
\begin{align*}
\text{Scheme 3-25 Synthesis of 6'-hydroxy-cinchonine 22.}
\end{align*}
\]

Furthermore, the benzyl chloride derivative 9-(chloromethyl)-(1,8-R;4,5-S)-1,2,3,4,5,6,7,8-octahydro-1,4:5,8-dimethanoanthracene 24 was synthesised by reduction of the aldehyde 25 to the corresponding alcohol 26 in 85 % yield. Subsequent substitution of the hydroxy function led to the chloride 24 in 96 % yield (Scheme 3-26, p.34).
Scheme 3-26 Synthesis of the 9-(chloromethyl)-(1,8-R;4,5-S)-1,2,3,4,5,6,7,8-octahydro-1,4:5,8-dimethanoanthracene 24.

According to the general procedure in Scheme 3-27, quaternisation of the quinidine derivatives with the corresponding benzyl chloride derivatives led to the quinidinium chlorides of substance library IV (Scheme 3-28).

Scheme 3-27 General synthetic procedure for the quaternisation of the quinidine derivatives.

The yields obtained in the synthesis of these quinidinium chlorides are summarised in Scheme 3-28, p.35.
Substance Library V. For the preparation of the cinchona-alkaloid based library V, quinidine 19 was first transformed to the derivative 27.

Cleavage of the aromatic ether function of quinidine 19 with BBr$_3$ led to the 6'-hydroxy-quinidine 22 in a yield of 61 %. Subsequent etherification with cyclopentylbromide 28 resulted in the desired quinidine derivative 27 in 84 % yield (Scheme 3-29, p.36).

*Test substrate IV-3 was synthesised by Dr. M. Guixà.*
For the synthesis of the benzyl chloride derivatives, 4-(trifluoromethyl)benzyl alcohol 29 was converted to the corresponding chloride 30 with PCl$_5$. The crude product was used for the synthesis of V-3 without further purification (Scheme 3-30).

Reaction of 4-iodobenzyl bromide 31 with tin-(IV)-chloride resulted in the formation of the corresponding 4-iodobenzyl chloride 32 (Scheme 3-31). Again, the crude product could be used directly in the next step without further purification.

Conversion of 2,4-difluorobenzylalcohol 33 with PCl$_5$ yielded the desired chloride 34. This was directly used in the synthesis of test substrate V-7, without further purification (Scheme 3-32).
For the synthesis of the benzylchloride 35, the corresponding aldehyde 36 was first reduced to the alcohol derivative 37. Subsequent substitution of the hydroxy function with PCl₅ led to the benzylchloride 35 (Scheme 3-33).

\[
\text{H}_2\text{C} = \text{O} \quad \xrightarrow{\text{NaBH}_4} \quad \text{H}_2\text{C} \text{HO} \quad \xrightarrow{\text{PCl}_5} \quad \text{H}_2\text{C} \text{Cl} \]

\[36 \xrightarrow{\text{NaBH}_4, \text{MeOH, } 0^\circ \text{C, } 3 \text{ h}} 37, 91\% \quad \xrightarrow{\text{PCl}_5, \text{toluene, r.t., } 18 \text{ h}} 35, 64\%\]

Scheme 3-33 Synthesis of 9-(chloromethyl)-1,2,3,4,5,6,7,8-octahydro-1,4:5,8-diethanoantracene 35.

According to the general procedure in Scheme 3-34, quaternisation of the quinidine derivatives with the corresponding chlorides led to the quinidinium chlorides of substance library V (Scheme 3-36).

\[
\begin{align*}
\text{N} & \quad \text{OR}_1 \\
\text{R} & \quad \text{Cl} \\
\text{THF, } 15 \text{ h} - 10 \text{ d, reflux} 
\end{align*}
\]

\[\text{OR}_1^1 \quad \text{R}_3 \quad \text{Cl}^{-} \]

Scheme 3-34 General synthetic procedure for the quaternisation of the quinidine derivatives.

In contrast to the general procedure, for the synthesis of test substrate V-1, quinidine 19 was first converted to the quaternary ammonium iodide 38 with methyl iodide in 70 % yield. The desired chloride V-1 was obtained by anion exchange with silver chloride in 75 % yield (Scheme 3-35).

\[
\begin{align*}
\text{OMe} & \quad \text{CH}_2 \\
\text{19} \quad \text{MeOH, r.t., } 24 \text{ h} \\
\text{OMe} & \quad \text{CH}_2 \\
\text{38, } 70\% \quad \xrightarrow{\text{AgCl, NH}_3, \text{H}_2\text{O}/\text{MeOH, r.t., } 72 \text{ h}} \quad \text{OMe} \\
\text{V-1, } 75\% 
\end{align*}
\]

Scheme 3-35 Synthesis of 1N-(methyl)quinidinium chloride V-1.

The synthetic yields of the substances of library V are shown in Scheme 3-36.
Scheme 3-36 Compounds contained in the cinchona alkaloid-based library V.
3.4 Experimental Part

3.4.1 Physiological ES cell screenings

The physiological tests were performed using a transgenic murine ES cell lineage expressing enhanced green fluorescent protein (EGFP) under the control of α-myosine heavy chain promoter (pα-MHC).

Culture of ES cells on mouse embryonic feeder cells. Transgenic mouse ES cells (αMHC Cl23) were cultured on 10 cm Petri dishes in Dulbecco’s-modified Eagle’s medium (DMEM) supplemented with 15 % fetal calf serum (FCS) and leukaemia inhibitory factor (LIF) on a layer of feeder cells (irradiated mouse embryonic fibroblasts). Cells were incubated at 37 °C, 7 % CO₂ and 95 % humidity. Cells were split every second day by trypsinising them to single cell suspension and seeding on a fresh dish coated with feeder cells.

ES cell aggregation. ES cells from one or more Petri dish were trypsinised, to obtain a single cell suspension, and collected by centrifugation. Cells were resuspended to a density of approximately 2·10⁶ cells/ml in Iscove’s modified Dulbecco’s medium (IMDM) supplemented with 20 % FCS. 4 ml per 6 cm Petri dish of this suspension were incubated on a rocking table at 50 rpm, 37 °C, 5 % CO₂ and 95 % humidity for 6 h. After this time the suspension was diluted 1:20 in several T25 tissue culture flasks and incubated for additional 18 h. Under these conditions ES cell aggregates (embryoid bodies) formed, typically around 500 per ml of cell suspension.

ES cell differentiation. The embryoid bodies (EBs) were cultured on 6-well-plates in IMDM supplemented with 20 % FCS. The test substrates were dissolved in DMSO (10⁻² M) and a dilution series was obtained by dilution with IMDM, 20 % FCS (10⁻³ M, 10⁻⁴ M, 10⁻⁵ M, 10⁻⁶ M). The EBs were treated with the test substrates and the corresponding dilutions and afterwards they were incubated at 37 °C, 5 % CO₂ and 95 % humidity for 14 d. After 7 d fresh IMDM, 20 % FCS and the test substrate were added. After 14 d the expressed EGFP was quantified. Therefore the EBs per well were counted and subsequently lysed with Triton X. The lysate was transferred to 96-well plates and the emitted fluorescence per well was determined.

The physiological ES cell screenings were performed according to the Cell Culture Quality Assurance Guide and the Standard Operating Protocols (SOP 3-01: Culture of
mES cells; SOP 3-02: Production of EBs by mass culture, SOP 4-01: R.E.Tox Test for embryotoxicity) developed by Axiogenesis AG, Köln, Department for cell culture, toxicology and assay developments. These procedures cannot be explained in detail, as they are subject to privacy regulations.

3.4.2 Synthesis of the Test Substrates

General Methods. Flash chromatography was performed on silica gel (Macherey-Nagel MN-Kieselgel 60, 230-240 mesh). TLC was performed on aluminium backed silica plates (Macherey-Nagel, Polygram© SIL G/UV254) which were developed by using UV fluorescence. Melting points were determined on a Büchi melting point apparatus and are uncorrected. $^1$H-NMR spectra were recorded at 300 MHz on Bruker AC 300 and DPX 300 instruments, respectively; $^{13}$C-NMR spectra were recorded at 75.5 MHz on a Bruker DPX 300 instrument. Chemical shifts ($\delta$) are given in parts per million (ppm) referenced to TMS. For the fine-structure interpretation the abbreviations of the signals are the following: s = singulet, d = doublet, t = triplet, q = quartet, m = multiplet. High resolution mass spectra (HR ESI-MS) were recorded on a Finnigan MAT 900 ST spectrometer. Infrared spectra were recorded on a Perkin Elmer Paragon 1000 FT-IR spectrometer using the ATR technique and on a Perkin Elmer 1600 Series FT-IR spectrometer. All commercially available chemicals were used without further purification. Compounds 25 and 36 were kindly provided by Sarwar Aziz. Anhydrous solvents were distilled from appropriate drying agents prior to use.

All experiments are characterised by a number within the bracket: [XX-SEE-XXX]. The roman number in front of the three-letter-code indicates the volume number of the laboratory notebook, whereas the number after the three-letter-code indicates the experiment number in the corresponding notebook volume.
3.4.3 Synthesis of \((1S,2R,4S,5R)-2,5\text{-Dihydroxybicyclo}[2.2.1]\text{heptane}\) (13)

\[
\begin{align*}

\text{12} \\
\text{13}
\end{array}
\end{align*}
\]

A solution of \([\text{Pd}(C_3H_5)\text{Cl}]_2\) (14.6 mg, 40 \(\mu\)mol, 0.05 mol\%) and (S)-MOP (78.7 mg, 168 \(\mu\)mol, 0.20 mol\%) in dry benzene (2 ml) was placed into a double-jacketed 50 ml Schlenk flask under argon. \(\text{HSiCl}_3\) (19.9 ml, 197 mmol, 2.40 equiv), distilled from quinoline, and quinoline (236 \(\mu\)l, 2.00 mmol, 2.43 mol\%) were added, and the solution was cooled to \(-3^\circ\text{C}\). Norbornadiene 12 (8.34 ml, 82.0 mmol, 1.00 equiv), passed through neutral alumina and subsequently distilled, was added slowly with magnetic stirring. The reaction mixture was stirred at \(-3^\circ\text{C}\) for 3 d, until it turned into a pale yellowish solid. The solvent and excess silane were removed in vacuo at r.t.. The residue was dissolved in dry \(\text{Et}_2\text{O}\) (50 ml) under argon and cooled to 0 \(^\circ\text{C}\). A mixture of dry MeOH (59.9 ml, 1.48 mol, 18.0 equiv), dry Et\(_3\)N (80.0 ml, 574 mmol, 7.00 equiv), and dry Et\(_2\)O (50 ml) was added dropwise. The solution was stirred at r.t. overnight. The precipitated salts were filtered off and washed with small quantities of Et\(_2\)O. The combined filtrates were concentrated in vacuo. To the residue was added KHF\(_2\) (32.0 mg, 410 mmol, 5.00 equiv), THF (80 ml), MeOH (80 ml) and \(\text{H}_2\text{O}_2\)-urea (57.8 g, 615 mmol, 7.50 equiv). The resulting white suspension was stirred overnight at 60 \(^\circ\text{C}\). After addition of a catalytic amount of MnO\(_2\), stirring was continued at r.t. for 4 h. The solids were filtered off, and the filter cake was washed with MeOH. The combined filtrates were concentrated in vacuo. The residue was dissolved in \(\text{H}_2\text{O}\) (100 ml) and extracted with a \(\text{CHCl}_3/\text{iPrOH}\) mixture (5 x 100 ml, 3:1). The combined organic phases were dried over MgSO\(_4\) and evaporated. The remaining solid was recrystallised from \(\text{CHCl}_3/n\text{-hexane}\) to give 3.82 g (30.0 mmol, 36 \%) of the diol 13 as thin colourless crystals.

\end{center}

Diol 13 (2.05 g, 16.0 mmol, 1.00 equiv) and powdered 3 Å molecular sieves (10 g) were suspended in CH\textsubscript{2}Cl\textsubscript{2} (250 ml). PCC (17.2 g, 80.0 mmol, 5.00 equiv) was added slowly and the resulting mixture was stirred at r.t. overnight. Et\textsubscript{2}O (100 ml) was added with vigorous stirring, and stirring was continued for 30 min. The mixture was then allowed to stand for 2 h. The liquid was filtered through Florisil (20 g, 80-150 µm). The black residue was extracted with CH\textsubscript{2}Cl\textsubscript{2}/Et\textsubscript{2}O (4 x 50 ml, 1:1) in an ultrasonic bath. The combined extracts were also filtered through the Florisil pad. Evaporation of the combined solutions yielded 1.21 g (9.75 mmol, 61 %) of the diketone 14 as a white solid.

3.4.8 Synthesis of (1R,3S)-3-Aminomethyl-3,5,5-trimethylcyclohexylamine (10)

[II-SEE-128]

(2R,3R)-2,3-Bis(benzoyloxy)butanedioic acid (1S,5R)-(5-amino-1,3,3-trimethylcyclohexyl)-methanamine salt (1:1) 17 (1.52 g, 2.88 mmol, 1.00 equiv) was dissolved in 5 M aq. NaOH (72 ml). The clear solution was extracted with CH\(_2\)Cl\(_2\) (4 x 20 ml), the combined organic phases were dried over Na\(_2\)SO\(_4\), and the main part of the solvent was evaporated. Vacuum distillation gave 437 mg (2.57 mmol, 89 %) of (1R,3S)-3-(aminomethyl)-3,5,5-trimethylcyclohexylamine 10 as a clear liquid (to be stored under argon).

C\(_{10}\)H\(_{22}\)N\(_2\) (170.3 g/mol)

\(^1\)H NMR (300 MHz, CHCl\(_3\)-d\(_1\)): \(\delta = 2.90-2.80\) (m; 1H), 2.22 (s; 2H), 1.50-1.44 (m; 1H), 1.40-1.33 (m; 1H), 1.07-1.03 (m; 1H), 0.97 (s; 4H), 0.89 (s; 3H), 0.86 (s; 3H), 0.79 (s; 3H), 0.83-0.59 (m; 3H).

\(^{13}\)C NMR (75.5 MHz, CHCl\(_3\)-d\(_1\)): \(\delta = 57.5, 50.4, 47.1, 45.7, 43.9, 36.4, 35.2, 31.9, 27.9, 23.8\).

The spectroscopical data are in agreement with the literature.\(^{55}\)
A 2 L beaker is charged with 300 ml of distilled water. L-(+)-tartaric acid 18 (118 g, 786 mmol, 1.00 equiv) is added with stirring in one portion. The solution is stirred as 1,2-diaminocyclohexane rac-10 (180 g, 1.57 mol, 2.00 equiv) and glacial acetic acid (82 ml) is added. An exothermic reaction was observed and the temperature rose up to 90 °C. The reaction mixture is allowed to cool to 5 °C, with stirring, over 4 h. The temperature is maintained at 5 °C for an additional hour and than the product is isolated by filtration. The crude product is washed with cold water (50 ml) followed by MeOH (4 x 50 ml). The filter cake is recrystallized from water (1.2 L). The solid is dissolved in CH₂Cl₂ (500 ml) and washed with 6 M aq. NaOH (3 x 100 ml) and brine (500 ml). The combined organic layers were dried over MgSO₄ and the solvent was removed under reduced pressure yielding 12.1 g (106 mmol, 13 %) (1R,2R)-1,2-diaminocyclohexane 10 as an off-white solid.

For the determination of the enantiomeric excess, a small amount of the product 10 was dissolved in 1 ml CH₂Cl₂, laced with one drop of trifluoroacetic anhydride, and analysed by chiral GC.

\[ \text{II-SEE-165} \]

![Chemical structure of 26 and 24](image)

Under argon atmosphere, alcohol 26 (730 mg, 3.04 mmol, 1.00 equiv) was dissolved in dry toluene (30 ml). The mixture was cooled to 0 °C and PCl$_5$ (1.06 g, 5.16 mmol, 1.70 equiv) was added. After stirring at r.t. for 18 h, saturated aq. NaHCO$_3$ (30 ml) was added at 0 °C, and the mixture was stirred for 10 min. The phases were separated and the aqueous layer was extracted with toluene (20 ml). The combined organic phases were washed with water (20 ml), dried over Na$_2$SO$_4$, filtered, and concentrated under reduced pressure to obtain 753 mg (2.91 mmol, 96 %) of the chloride 24 as colourless solid.
3.4.19 Synthesis of 9-O-Methylquinidine (20)

[II-SEE-122]

Under argon atmosphere, NaH (55 % dispersion in mineral oil) (336 mg, 7.70 mmol, 2.50 equiv) was added to a solution of quinidine 19 (1.00 g, 3.08 mmol, 1.00 equiv) in DMF (10 ml) and the suspension was stirred at r.t. for 2 h. Methyl iodide 23 (211 µl, 5.19 mmol, 1.70 equiv) was added dropwise with stirring over 10 min. The mixture was stirred at r.t. for 15 h. The reaction mixture was quenched with ice and acidified with 1N HCl. The mixture was extracted with EtOAc and washed with water and brine. The organic layer was dried over Na2SO4 and concentrated in vacuo. The crude residue was purified by silica-gel column chromatography (hexanes/ethyl acetate 9:1). The product was obtained as a white solid (205 mg, 65%).
481 mg, 3.39 mmol, 1.10 eq) was added dropwise within 10 min and the mixture was stirred for 13 h at r.t. The reaction was quenched with brine (10 ml) and the phases were separated. The aqueous layer was extracted with EtOAc (3 x 7 ml) and the organic layer was washed with brine (20 ml). The combined organic layers were dried over Na₂SO₄ and the solvent was removed under reduced pressure. The residue was purified by flash chromatography (CHCl₃/MeOH 5:1) to yield 940 mg (2.78 mmol, 90%) of the product 29 as yellow oil.

\]

In a Schlenk flask, boron tribromide (3.09 g, 12.3 mmol, 4.00 equiv) in dry CH\textsubscript{2}Cl\textsubscript{2} (12 ml) was slowly added under vigorous stirring to a solution of quinidine 19 (1.00 g, 3.08 mmol, 1.00 equiv) in dry CH\textsubscript{2}Cl\textsubscript{2} (100 ml) at -78 °C. The reaction mixture was allowed to warm up to r. t. It was refluxed at 40 °C for 1 h and then cooled to 5 °C. While stirring and maintaining the temperature aq. NaOH (10 %, 30 ml) was added. The aqueous solution was separated from the organic phase and was washed with CH\textsubscript{2}Cl\textsubscript{2} (30 ml). HCl (2 M) was added dropwise until a colourless solid precipitated (approx. pH 8). Extraction with CHCl\textsubscript{3}, drying of the organic phase over MgSO\textsubscript{4} and evaporating to dryness yielded 580 mg (1.87 mmol, 61 %) of the desired product 22 as yellowish solid.

3.4.26 Synthesis of 1-N-(9-Anthrylmethyl)quinidinium chloride (IV-6)

[II-SEE-117]

\[
\begin{align*}
19 & \quad 45 & \quad \text{IV-6} \\
\text{19 + 45} & \quad \text{THF, reflux, 16 h} & \quad \text{IV-6, 36%}
\end{align*}
\]
Under argon atmosphere, quinidine 19 (1.00 g, 3.08 mmol, 1.00 equiv) and 9-chloromethylanthracene 45 (768 mg, 3.08 mmol, 1.00 equiv) were dissolved in dry THF (25 ml), and the solution was refluxed for 16 h. The precipitate was filtered off and was washed with THF. The solid was redissolved in CH$_2$Cl$_2$ (10 ml) and was added dropwise to Et$_2$O (150 ml). The suspension was stirred for 15 min, the precipitate was filtered off and was dried in vacuo. The crude product was purified by flash chromatography (CHCl$_3$/MeOH 9:1 → 6:1) to yield 617 mg (1.12 mmol, 36 %) of the product IV-6 as a yellow solid.

\]

Under argon atmosphere, PCl\(_5\) (4.02 g, 19.3 mmol, 1.70 equiv) was added to 4-(trifluoromethyl)benzyl alcohol 29 (1.56 ml, 2.00 g, 11.4 mmol, 1.00 equiv) in dry toluene (100 ml) and the reaction mixture was stirred for 18 h at r.t.. Saturated aqueous NaHCO\(_3\) solution (100 ml) was added and the mixture was stirred for 15 min. The organic layer was separated and dried over Na\(_2\)SO\(_4\). The solvent was removed under reduced pressure and the residue was used for the synthesis of 1-N-(4-trifluoromethyl-benzyl)quinidinium chloride V-3 without further purification.

Under argon atmosphere, cesium carbonate (1.31 g, 4.03 mmol, 2.50 equiv) and cyclopentyl bromide 28 (345 µl, 450 mg, 3.22 mmol, 2.00 eq) were added to a solution of 6’-hydroxycinchonine 22 (500 mg, 1.61 mmol, 1.00 equiv) in dry DMF (60 ml). The reaction mixture was stirred for 40 h at 60 °C. After cooling to r.t., the solids were filtered off and the filtrate was concentrated under reduced pressure. The residue was dissolved in CHCl₃ (20 ml) and was washed with dist. H₂O (20 ml). The solvent was removed under reduced pressure and the residue was dried in vacuo to yield 510 mg (1.35 mmol, 84 %) of the product 27 as light orange solid.

4 A Simplified Synthesis of Takemoto’s Catalyst

4.1 Background

Urea and thiourea derivatives have been subject to extensive investigations in the area of molecular recognition due to their strong hydrogen-bonding ability. Kelly and Etter reported that (thio)urea not only recognise organic compounds but also activate substrates by acting as general acidic catalysts. Since then, novel urea and thiourea derivatives have been developed for a variety of diastereo- and enantioselective reactions. Their versatility as general acids has been successfully demonstrated by several groups. However, the use of these catalysts for enantioselective reactions has been rather limited as ureas are less acidic than metallic Lewis acids. To address this problem, bifunctional thiourea catalysts have been developed, which activate the nucleophile by deprotonation and the electrophile by hydrogen bonding (Scheme 4-1). Among the bifunctional systems developed, Takemoto’s catalyst is the most prominent. A significant number of C-C couplings, for example, Michael-, Mannich-, aza-Henry- reactions, or the alcoholytic dynamic kinetic resolution of azlactones are catalysed enantioselectively by Takemoto’s bifunctional aminothiourea derivative 51.

![Scheme 4-1](image.png)

Scheme 4-1 Principle of the dual activation by bifunctional (thio)ureas (left), amino thiourea 51 (Takemoto’s catalyst, right).

The original synthesis of Takemoto’s catalyst 51 involves the addition of isothiocyanate 43 to N,N-dimethyl-trans-1,2-diaminocyclohexane 52 (Scheme 4-2).
The main drawback of this approach is the laborious synthesis of the \(N,N\)-dimethyl-\(trans\)-1,2-diaminocyclohexane building block 52, which was first described by Finney and coworkers in 2000.\(^6\) As shown in Scheme 4-3, condensation of (\(1R,2R\))-1,2-diaminocyclohexane 11 with the Pinner salt 53 derived from acetonitrile provides the corresponding imidazoline 54. Refluxing a solution of 54 in ethanol-water mixture leads to the corresponding mono-acetyl diamine 55. The diamine 55 is converted to the \(N,N\)-dimethyl derivative 56 by reductive amination, followed by acidic cleavage of the acetamide 56.

An alternative approach for the synthesis of the \(N,N\)-dimethyl-\(trans\)-1,2-diaminocyclohexane building block 52 was described in 2003 by Kaik and Gawronski.\(^7\) The desired compound 52 was synthesised via a monoprotection of the (\(1R,2R\))-1,2-diaminocyclohexane 11 with phthalic anhydride 57. However, this approach also involves a tedious four-step procedure (Scheme 4-4).

---

**Scheme 4-3** Synthesis of \(N,N\)-dimethylanine 52 according to Finney.\(^6\)
In the first step, mono-protection of the \((1R,2R)-1,2\)-diaminocyclohexane 11 is achieved by reaction with phthalic anhydride 57 in the presence of \(p\)-toluenesulfonic acid 58. Deprotonation of the corresponding salt 59 yields the mono-protected diamine 60. Reductive amination affords the \(N'\)-phthaloyl-protected \(N, N\)-dimethylamine 61. Finally, deprotection yields the desymmetrized \(N, N\)-dimethyl diamine 52.

### 4.2 Concept

An improved synthesis of Takemoto’s catalyst 51 could be realised in two steps if the readily available and cheap \((1R,2R)-1,2\)-diaminocyclohexane 11 can be transformed to the mono-thiourea 62. A subsequent dimethylation would lead to the fully assembled catalyst 51. A literature survey afforded valuable information regarding the synthesis of mono-thiourea derivatives of diamines:

Connon and coworkers reported the direct addition of the \((1R,2R)-1,2\)-diaminocyclohexane 11 to isothiocyanate 43 in 49 % yield (Scheme 4-5). \(^{70}\)

![Scheme 4-5 Synthesis of the mono-thiourea 62 as reported by Connon. \(^{70}\)](image)

However, in our hands, following Connon’s procedure led to the bis-thiourea 63 in 86 % yield from equimolar amounts of 43 and 11 (Scheme 4-6). This observation has been confirmed by several other working groups. \(^{71,72}\)

![Scheme 4-6 Formation of the bis-thiourea derivative 63, following Connon’s protocol. \(^{71,72}\)](image)
The formation of the corresponding bis-thiourea 63 could be avoided either (1) by mono-protection of the diamine 11 or (2) by decreasing the reactivity of the isothiocyanate 43.

(1) Since covalent mono-protection of the diamines is normally accompanied by two additional protection/deprotection steps, this approach seems to be less favorable. In principle, the diamine 11 could be also protected as an ammonium chloride 64, since the HCl “protecting group” can be cleaved in situ with NaBH₃CN in the following methylation step (Scheme 4-7).

![Scheme 4-7 Proposed addition of isothiocyanate 43 to the HCl mono-protected diamine 64 and in situ cleavage of the protecting group in the following methylation step.]

However, as described by Moreau, the addition of aromatic isothiocyanate 43 to HCl mono-protected (1R,2R)-1,2-diaminocyclohexane 64 does not result in the corresponding mono-thiourea 65. Instead, the guanidine derivative 66 is formed by cyclisation of the thiourea 65 and elimination of H₂S (Scheme 4-8).

![Scheme 4-8 Formation of guanidine derivative 66 by addition of isothiocyanate 43 to HCl mono-protected diamine 64.]

(2) The group of Nagasawa observed that the urea analogue 67 can be prepared by condensation of 3,5-bis(trifluoromethyl)aniline 68 with 4-nitrophenylchloroformate 69 followed by addition of (1R,2R)-1,2-diaminocyclohexane 11 (Scheme 4-9, p. 94).

Rivier and coworkers\textsuperscript{74} reported the reaction of aniline 70 with phenyl chlorothiocarbonate 71 to form phenyl thiophenylcarbamate 72 (Scheme 4-10). Furthermore, when stirring the phenyl thiophenylcarbamate 72 in CH$_2$Cl$_2$ at r.t. Schneider\textsuperscript{75} observed its slow decomposition to the corresponding isothiocyanate 39 and phenol 73 (Scheme 4-10).

Based on the work of Rivier\textsuperscript{74} and Schneider\textsuperscript{75} the reaction described by Nagasawa\textsuperscript{8} (Scheme 4-9) can be interpreted as follows:

\begin{equation}
\begin{array}{c}

\text{42} \\
\text{67, 73 %} \\
\end{array}
\end{equation}

\textbf{Scheme 4-11} Proposed formation of intermediate 74.
The aniline derivative 68 first reacts with 4-nitrophencylchloroformate 69 to form the corresponding intermediate 74. Then it reacts either directly with the (1R,2R)-1,2-diaminocyclohexane 11 with elimination of the phenolate moiety or first decomposes to the isocyanate 42 which adds to (1R,2R)-1,2-diaminocyclohexane 11 (Scheme 4-11, p. 94).

Since the reaction of intermediate 74 with the diamine 11 yields only the mono-thiourea, it can be assumed that intermediate 74 represents a less reactive synthetic equivalent for isocyanate 43.

Hence, to obtain the desired thiourea equivalent 62, 4-nitrophencylchloroformate 69 could be replaced by a suitable, commercially available thio-analogue, e.g. 71, 76, and 77 (Scheme 4-12).

![Scheme 4-12](image)

Scheme 4-12 Thiocarbonyl derivatives for the synthesis of thiourea 62.

Finally, methylation of the primary amino function should yield the desired Takemoto’s catalyst 51 (Scheme 4-13).

![Scheme 4-13](image)

Scheme 4-13 Methylation with formaldehyde.
4.3 Results and Discussion

The approach for the synthesis of the thiourea 62 proceeds via the reaction of aniline derivative 68 with the Staab-reagent 76, thiophosgene 77 or phenyl chlorothioformate 71 according to the synthetic procedure described by Nagasawa\(^8\) (Scheme 4-14).

Unfortunately, neither employing thiophosgene 77 nor the Staab-reagent 76 led to the desired product 62. Using thiophosgene 77 resulted in the formation of bis-thiourea 63 in 84 % yield (Scheme 4-15).

Application of the Staab-reagent 76 led predominantly to the formation of trans-4,5-tetramethyleneimidazolidine-2-thione 81 (Scheme 4-16).

Using phenyl chlorothioformate 71, the desired mono-thiourea 62 was obtained in 35 % yield (Scheme 4-17, p. 97).
Based on the different reactivities of the thiocarbonyl compounds 71, 76 and 77 an explanation for the observed differences may be as follows:

The very electrophilic thiophosgene 77 couples with the aniline derivative 68 to the highly reactive intermediate 80, which then reacts with the diamine 11 to form the mono-thiourea 62. After mono-thioacylation, the diaminocyclohexane derivative 62 should exhibit a lower NH₂-nucleophilicity than the free diaminocyclohexane 11. Despite of that, the high electrophilicity of the intermediate 80 leads to fast bis-thioacylation and therefore results in the formation of the bis-thiourea 63 (Scheme 4-18).

The less electrophilic Staab-reagent 76 does not react with the weakly nucleophilic NH₂-function of the aniline derivative 68, but with the more nucleophilic NH₂-function of the diamine 11, forming the cyclic thiourea 81 (Scheme 4-18).
In contrast, the phenyl chlorothioformate 71 has nucleofuges (Cl, OPh) with rather different reactivities. The more reactive Cl-leaving group is substituted by the weakly nucleophilic NH₂-group of the aniline derivative 68. The intermediate formed 78 is less reactive than intermediate 80. Therefore, reaction with diaminocyclohexane 11 leads predominantly to the desired mono substituted amino thiourea 62 (Scheme 4-18, p. 97).

To improve the yield of the mono-thiourea 62, different reaction conditions were screened, based on the original reaction protocol[8] [values in parentheses] (Scheme 4-19). Stirring the solution of the aniline derivative 68 and phenyl chlorothioformate 71 for 2 h [5 min] and using a 1.8 M [2.7 M] solution of the diamine 11 led to an optimised yield of 50 % by using only 1.0 eq of the diamine 11 [3.0 eq] and 1.0 eq of Hüning’s base [3.0 eq] (Scheme 4-20).

Scheme 4-19 Reaction protocol according to Nagasawa.[8]

Scheme 4-20 Reaction protocol after optimisation.

The final step in the synthesis of Takemoto’s catalyst 51 is the reductive methylation of the free primary amino function with formaldehyde. In a screening for the most suitable reducing agent (Table 4-1, p. 99), zinc powder proved best (Table 4-1, entry 2, 73 %).

In conclusion, an efficient two-step synthesis of Takemoto’s catalyst 51, using commercially available starting materials has been developed. As the key step, the amino thiourea 62 was prepared by condensation of 3,5-bis(trifluoromethyl)aniline 68 with phenyl chlorothioformate 71, and substitution of phenol by trans-1,2-diaminocyclohexane 11. Reductive dimethylation with formaldehyde / zinc yielded Takemoto’s catalyst 51 in an overall yield of 37 %.

4.4 Experimental Part

4.4.1 General Experimental Conditions

Flash chromatography was performed on silica gel (Macherey-Nagel, MN-Kieselgel 60, 230-240 mesh). TLC was performed on aluminium backed silica plates (Macherey-Nagel, Polygram© SIL G/UV254), detection by UV fluorescence. Melting points were determined on a Büchi melting point apparatus and are uncorrected. ¹H-NMR spectra were recorded at 300 MHz on a Bruker DPX 300 instrument; ¹³C-NMR spectra at 75.5 MHz. Chemical shifts (δ) are given in parts per million (ppm) referenced to TMS. For the fine-structure interpretation the abbreviations of the signals are the following: s = singulet, d = doublet, t = triplet, q = quartet, m = multiplet. High resolution mass spectra (HR ESI-MS) were recorded on a Finnigan MAT 900 ST spectrometer. Infrared spectra were recorded on a Perkin-Elmer Paragon 1000 FT-IR spectrometer using the ATR
technique and on a Perkin Elmer 1600 Series FT-IR spectrometer. All commercially available chemicals were used without further purification.

All experiments are characterised by a number within the bracket: [XX-SEE-XXX]. The roman number in front of the three-letter-code indicates the volume number of the laboratory notebook, whereas the number after the three-letter-code indicates the experiment number in the corresponding notebook volume.

### 4.4.2 Preparation of trans-4,5-Tetramethyleneimidazolidine-2-thione (81)

1,1'-thiocarbonyl diimidazole 76 (806 mg, 4.52 mmol, 1.00 equiv) was added to a solution of 3,5-bis(trifluoromethyl)aniline 68 (700 µl, 1.03 mg, 4.52 mmol, 1.00 equiv) in CH₂Cl₂ (15 ml) at r.t.. The mixture was stirred for 5 min, then added dropwise to a solution of (1R,2R)-1,2-diaminocyclohexane 11 (1.54 g, 13.5 mmol, 3.00 equiv) in CH₂Cl₂ (5 ml) and the resulting mixture was stirred for 15 min. Saturated aq. NaHCO₃ (20 ml) was added and the phases were separated. The aqueous layer was extracted with CH₂Cl₂ (3 x 15 ml). The combined organic layers were washed with brine (40 ml) and dried over MgSO₄. The solvent was removed under reduced pressure and the residue was purified by flash chromatography (CHCl₃/MeOH 8:1) to give the product 81 as light yellow crystals (491 mg, 3.14 µmol, 70 %).

[III-SEE-247] (Scheme 4-19, p. 98)\(^{6}\)

Phenyl chlorothioformate 71 (250 µl, 312 mg, 1.81 mmol, 1.00 equiv) was added to a solution of 3,5-bis(trifluoromethyl)aniline 68 (280 µl, 410 mg, 1.82 mmol, 1.00 equiv) and pyridine (160 µl, 157 mg, 1.99 mmol, 1.10 equiv) in CH₂Cl₂ (6 ml) at r.t.. The mixture was stirred for 5 min, then added dropwise to a solution of (1R,2R)-1,2-diamino-cyclohexane 11 (620 mg, 5.43 mmol, 3.00 equiv) in CH₂Cl₂ (2 ml). N,N-Diisopropylethylamine (896 µl, 699 mg, 5.43 mmol, 3.00 eq) was added and the mixture was stirred for 15 min. Saturated aq. NaHCO₃ (7 ml) was added, the phases were separated, and the aqueous layer was extracted with CH₂Cl₂ (3 x 5 ml). The combined organic layers were washed with brine (10 ml) and dried over MgSO₄. The solvent was removed under
reduced pressure and the residue was purified by flash chromatography (CHCl₃/MeOH 7:1) to give the product 62 as light yellow crystals (245 mg, 638 µmol, 35 %).

[IV-SEE-288] (Scheme 4-20, p. 98)
Phenyl chlorothioformate 78 (250 µl, 312 mg, 1.81 mmol, 1.00 equiv) was added to a solution of 3,5-bis(trifluoromethyl)aniline 68 (280 µl, 410 mg, 1.82 mmol, 1.00 equiv) and pyridine (160 µl, 157 mg, 1.99 mmol, 1.10 equiv) in CH₂Cl₂ (6 ml) at r.t.. The mixture was stirred for 2 h, then added dropwise to a solution of (1R, 2R)-1,2-diaminocyclohexane 11 (207 mg, 1.81 mmol, 1.00 equiv) in CH₂Cl₂ (1 ml). N,N-Diisopropyl-ethylamine (300 µl, 234 mg, 1.81 mmol, 1.00 eq) was added and the mixture was stirred for 15 min. Saturated aq. NaHCO₃ (7 ml) was added, the phases were separated, and the aqueous layer was extracted with CH₂Cl₂ (3 x 5 ml). The combined organic layers were washed with brine (10 ml) and dried over MgSO₄. The solvent was removed under reduced pressure and the residue was purified by flash chromatography (CHCl₃/MeOH 7:1) to give the product 62 as light yellow crystals (351 mg, 911 µmol, 50 %).

4.4.5 1-[3,5-Bis(trifluoromethyl)phenyl]-3-[(1R,2R)-2-(dimethylamino)cyclohexyl]-thiourea (51, Takemoto’s Catalyst)

![Chemical Structures]

[IV-SEE-292] (Table 4-1, Entry 1, p. 99)

Under argon atmosphere, a mixture of the aminothiourea 62 (110 mg, 285 µmol, 1.00 equiv) in toluene (1.5 ml) and aqueous formaldehyde 37 % (55.0 µl, 684 µmol, 2.40 equiv) was treated with Hantzsch ester (216 mg, 8.55 µmol, 3.00 equiv) and thiourea (2.10 mg, 28.5 µmol, 10.0 mol%). The mixture was stirred at 60 °C for 72 h. After filtration through celite, the solvent was evaporated and the residue was purified by flash chromatography (CHCl₃/MeOH 7:1). The product 51 was obtained as an off-white crystalline solid (32.0 mg, 77.0 µmol, 27 %).

[IV-SEE-296] (Table 4-1, Entry 2, p. 99)

Zinc powder (102 mg, 1.56 mmol, 4.00 equiv), AcOH (180 µl, 187 mg, 3.12 mmol, 8.00 equiv) and aqueous formaldehyde 37 % (95.0 µl, 1.17 mmol, 3.00 equiv) were added to a solution the of aminothiourea 62 (150 mg, 389 µmol, 1.00 equiv) in dioxane (0.5 ml), and the resulting mixture was stirred for 72 h at r.t.. Aqueous NH₃ (500 µl) was added, the aqueous phase was extracted with CH₂Cl₂ (2 x 1 ml) and dried over MgSO₄. The solvent was removed under reduced pressure and the residue was purified by flash chromatography (CHCl₃/MeOH 7:1). The product 51 was obtained as an off-white crystalline solid (117 mg, 283 µmol, 73 %).
Aqueous NaH$_2$PO$_3$ solution (2 M, 1.4 ml, 2.85 mmol, 10.0 equiv) and aqueous formaldehyde 37 % (231 µl, 2.85 mmol, 10.0 equiv) were added to a solution of the amino thiourea 62 (110 mg, 285 µmol, 1.00 equiv) in dioxane (1.4 ml). The resulting mixture was stirred for 1 h at 60 °C. The pH was adjusted to 8 by addition of aqueous NaOH (2 M) and the reaction mixture was extracted with CH$_2$Cl$_2$ (3 x 3 ml). The organic layer was dried over MgSO$_4$, the solvent was removed under reduced pressure and the residue was purified by flash chromatography (CHCl$_3$/MeOH 7:1). The product 51 was obtained as an off-white crystalline solid (80.0 mg, 193 µmol, 68 %).

A mixture of the amino thiourea 62 (313 mg, 812 µmol, 1.00 equiv), formic acid (337 µl, 8.94 mmol, 11.0 eq) and aqueous formaldehyde 37 % (149 µl, 1.79 mmol, 2.20 equiv) was stirred under reflux for 6 h. The solvent was removed under reduced pressure and the residue was dissolved in CH$_2$Cl$_2$ (500 µl) and washed with saturated NaHCO$_3$ (500 µl) solution. The organic layer was dried over MgSO$_4$, the solvent was evaporated and the residue was purified by flash chromatography (CHCl$_3$/MeOH 7:1). The product 51 was obtained as an off white crystalline solid (15.0 mg, 36.0 µmol, 4 %).

Aqueous formaldehyde 37 % (252 µl, 3.38 mmol, 5.00 equiv) was added to a solution of the amino thiourea 62 (260 mg, 675 µmol, 1.00 equiv) in acetonitrile (5 ml), and the resulting mixture was stirred for 15 min at r.t.. NaBH$_3$CN (85.0 mg, 1.35 mmol, 2.00 equiv) was added, followed by acetic acid (85.0 mg, 1.35 mmol, 2.00 equiv) after 15 min. After stirring at r.t. for 2 h, the reaction mixture was diluted with 2 % MeOH/CHCl$_3$ mixture (10 ml) and washed with 1 N NaOH solution (12 ml). The aqueous layer was extracted with CHCl$_3$ (3 x 6 ml), the combined organic layers were dried over MgSO$_4$, and the solvent was removed under reduced pressure. The residue was purified by flash chromatography (CHCl$_3$/MeOH 7:1). The product 51 was obtained as an off-white crystalline solid (90.0 mg, 218 µmol, 32 %).

5 Enantioselective Aza-Baylis-Hillman Reaction Catalysed by a La-linked-BINOL Complex

5 La-linked BINOL Catalysed Asymmetric Aza-BH Reaction

5.1 Background

The Morita-Baylis-Hillman reaction has developed to a highly efficient C-C bond forming process since it combines two important requirements: atom economy and functional group generation. Although it has been discovered as early as 1968 by Morita (phosphine-catalysis) and was successively further improved in 1972 by Baylis and Hillman (amine-catalysis), the reaction and its applications have received a growing interest only since the mid 1990s.

The Morita-Baylis-Hillman reaction consists of a C-C coupling between the α-position of an EWG-substituted olefin and a carbonyl group in the presence of an appropriate nucleophilic catalyst, e.g. a tertiary amine or a phosphine. The transformation leads to the formation of a multifunctionalised molecule (Scheme 5-1, left).

Replacing the carbonyl by an imine leads to the aza-Baylis Hillman reaction (Scheme 5-1, right). This reaction yields α-methylene-β-amino derivatives and, in particular, β-amino esters if acrylates are used as Michael acceptors.

5.1.1 Mechanistic Studies

Both the Baylis-Hillman- (BH) and aza-Baylis-Hillman (aza-BH) reactions are based on an addition-elimination sequence. The generally accepted mechanism of the aza-Baylis-Hillman reaction is shown in Scheme 5-2, p.109. After addition of a nucleophile to the olefin (A), the resulting enolate adds to the imine (B). A proton transfer (C), followed by the elimination of the catalyst (D) and the release of the aza-Baylis-Hillman adduct.
Enantioselective aza-BH Reaction Catalysed by a La-linked-BINOL Complex

Scheme 5-2 Proposed mechanism of the aza-BH reaction.

*Jacobsen et al.* reported aza-BH reactions of methyl acrylate and nosylimines in CHCl₃ catalysed by DABCO. The initial rates were found to follow Equation (5-1).

\[
\text{rate} = \frac{a[DABCO][Acrylate][Imine]}{1 + b[Imine]} \quad (5-1)
\]

A prominent primary kinetic isotope effect \(k_H/k_D = 3.81\) was observed after comparison of the initial reaction rates of methyl acrylate with the corresponding \(\alpha\)-deutero-methyl acrylate, suggesting that deprotonation of the \(\alpha\)-H(D) (step C) was rate limiting. *Leitner et al.* analysed the PPh₃ catalysed aza-Baylis-Hillman reaction between methyl vinyl ketone and a fluorinated \(N\)-tosylated imine in THF. Initial rates are shown as a function of concentration for the individual components (Equation 5-2). The order of 0.5 for the imine indicates that the rate-determining step (RDS) is influenced by the proton transfer.

\[
\text{rate} = k_{obs}[PPh₃]^{1}[MVK]^{1}[Imine]^{0.5} \quad (5-2)\quad \text{rate} = k_{obs}[PPh₃]^{1}[MVK]^{1}[Imine]^{0.5} \quad (5-3)
\]

Examination of the kinetics in the presence of phenol as a prototypical additive revealed that the rate law of the reaction changes in the presence of a Brønsted acid, showing first order dependence for the imine (Equation (5-3)). Hence, the elimination step is no longer involved in the RDS and the proton transfer is accelerated by the protic additive.
5.1.2 Substrate Diversity

**Imines.** Various activated aromatic aldimines like tosyl- (Ts-) imines, nosyl (Ns-) imines, 2-trimethylsilylethanesulfonyl- (SES-) imines, chiral sulfonyl- and thiophosphorylimines, diphenylphosphinoyl- (dpp-) imines, and very recently, even *in situ* generated tert-butyloxycarbonyl- (Boc-) and carboxybenzyl- (Cbz-) imines can be used as electrophiles in aza-BH reactions. However, the reaction outcome strongly depends on the appropriate protecting group, as highly activated imines are required for most aza-BH reactions.

Tosylimines are the most often employed imines in the aza-BH reaction. Since the Ts-protecting group exhibits a strong electron withdrawing effect, the resulting imines are very electrophilic. However, harsh conditions are required to cleave the Ts-protecting group. This limits the synthetic utility of the amino adducts as many functional groups do not tolerate these conditions (Scheme 5-3).

![Scheme 5-3 Cleavage of the Ts-protecting group.](image)

Although the Ns- and SES-protecting groups also lead to highly electrophilic imines, these groups are rarely used in the aza-BH reaction. Even though the SES-protecting group can be easily removed under relatively mild conditions (Scheme 5-4, (b)), the laborious four-step synthesis of SES-imines is the main drawback (Scheme 5-4, (a)).

![Scheme 5-4 Synthesis (a) and cleavage (b) of the SES-protecting group.](image)

---

iv For the application of chiral imines see: 5.1.3 Development of Asymmetric Aza-Baylis-Hillman Reactions
The use of Ns-imines is rather unusual as the Ns-protecting group cannot be cleaved off from the aza-BH adduct. The cleaving thiol reagents add to the double bond of the products instead of deprotecting the amino function (Scheme 5-5).

Phosphinoylimines can be easily synthesised and their dpp-protecting group can be removed under mild conditions. However, dpp-protected imines are rarely used in aza-BH reactions, since they are weaker electrophiles compared to their sulfonlated analogues (Scheme 5-6).

Recently, several working groups explored the use of in situ generated imines in aza-BH reactions. For example, Gajda et al. described the DABCO catalysed reaction between electron deficient alkenes and Boc- or Cbz-protected imines, generated in situ from stable N-carbamate protected amidoalkyl-p-tolylsulfones (Scheme 5-7).

In contrast to aromatic imines the use of aliphatic imines in aza-BH reactions is poorly illustrated in literature. Indeed, activated aliphatic imines are enolisable, are more tedious to synthesise, are less stable, and their application in aza-BH reactions gave poorer results compared to their aromatic counterparts.
It is possible to synthesise the imine electrophile in the aza-BH reaction *in situ* from the corresponding aldehyde and the diphenylphosphinamid, SES-NH₂, tosylamide, or Boc-amide as it is shown in Scheme 5-8.

**Scheme 5-8** One-pot procedure of the aza-BH reaction.

**Enone components.** Vinyl ketones and acrylates are the most frequently employed enone components. Vinyl ketones are particularly interesting substrates due to their versatile applicability in aza-BH reactions while the use of acrylates in the aza-BH reaction gives synthetically valuable β-amino acid esters. The use of cyclic enones, activated allenes, alkynes and conjugated dienes, acrylonitrile, nitroalkenes, acrylamide, and acroleine as enone components in the aza-BH reaction is less common.

### 5.1.3 Development of Asymmetric Aza-Baylis-Hillman Reactions

**Chiral Imines.** The first example of an asymmetric aza-BH reaction has been developed by Kündig *et al.* in 1994. Chiral planar Cr-complexes of sulfonylimines derived from *ortho*-substituted aromatic aldehydes were utilised. The chiral aldehydes were first transformed into tosylimines and then reacted with Michael acceptors in the presence of DABCO to give α-methylene-β-amino esters in good yields and good enantiomeric excesses. At the end of the reaction, the Cr(CO)₃ group is removed oxidatively. The main disadvantage of this method is the applicability only to imines derived from *ortho*-substituted aromatic aldehydes (Scheme 5-9).

**Scheme 5-9** Diastereoselective aza-BH reaction with enantiopure planar chiral o-substituted Cr(CO)₃.
Later on, Aggarwal et al.\textsuperscript{87c} employed enantiopure $N$-sulfinimines in aza-BH reactions with methyl acrylate in the presence of 3-hydroxyquinuclidine (3-HQD) and a Lewis acid. The desired products were obtained in good to moderate diastereoselectivities (Scheme 5-10).

\begin{equation}
\begin{array}{c}
\text{R}^1 \text{H} \quad \text{R}^2 \text{N SO}_\text{R}^2 \\
\quad + \quad \text{O} \quad \text{Me} \quad \text{R}^1 \text{C} = \text{NH} \quad \text{OR}^2 \\
\quad + \quad \text{HN SO} \quad \text{R}^2 \text{CO}_\text{Me} \\
\quad + \quad \text{HN SO} \quad \text{R}^2 \text{CO}_\text{Me} \\
\text{R}^1 = \text{p-Tol, tBu} \\
\text{R}^2 = \text{Ph, 4-NO}_2\text{C}_6\text{H}_4, \text{nPr} \\
\end{array}
\end{equation}

\textbf{Scheme 5-10} Use of enantiopure $N$-sulfinimines in aza-BH reactions with methyl acrylates.\textsuperscript{87c}

Subsequently, enantiopure sulfinimines were also used by Shi et al.\textsuperscript{87d} for reactions with cyclopentenone. Good yields and diastereoselectivities were achieved (Scheme 5-11).

\begin{equation}
\begin{array}{c}
\text{O} \quad \text{N SO}_\text{p-Tol} \\
\quad + \quad \text{O} \quad \text{p-Tol} \text{OS} \quad \text{O} \\
\quad + \quad \text{p-TolOS} \quad \text{O} \\
\text{R} = \text{Ph, C}_6\text{H}_5\text{CH}_2\text{CH}_2, 4-\text{ClC}_6\text{H}_4, \\
4-\text{BrC}_6\text{H}_4, 3-\text{FC}_6\text{H}_4, \text{Me(CH}_2)_3 \\
\end{array}
\end{equation}

\textbf{Scheme 5-11} Diastereoselective aza-BH reaction with enantiopure $N$-sulfinimines according to Shi.\textsuperscript{87d}

The $N$-sulfinyl groups not only induce high selectivity but also exhibit the advantage of being easily removed under relatively mild conditions. Their synthesis usually requires several steps\textsuperscript{99} but a fast one-pot synthesis of chiral $N$-$p$-toluenesulfinylimines starting from a commercial chiral sulfinate has also been developed.\textsuperscript{100}

Recently, Zhou et al.\textsuperscript{101} used BINOL-based $N$-thiophosphoryl imines as chiral substrates in the 1,3,5-triaza-phosphaadamantane (PTA) catalysed aza-BH reaction and obtained excellent diastereomeric excesses and good yields (Scheme 5-12).

\begin{equation}

\end{array}
\end{equation}

\textbf{Scheme 5-12} BINOL-based $N$-thiophosphoryl imines in the aza-BH reaction with methyl vinyl ketone.\textsuperscript{101}
Chiral Nucleophiles - Amines. The first asymmetric aza-Baylis-Hillman reaction with chiral amines as catalysts was published by Shi et al.\textsuperscript{102} in 2002. Based on the work of Hatakeyama\textsuperscript{103} who first employed \(\beta\)-isocupreidine \textsuperscript{82} as a chiral catalyst in the MBH-reaction, Shi and co-workers used this chiral amine quinidine derivative in the reaction between \(N\)-sulfonyl imines and various activated alkenes. The corresponding adducts were obtained in moderate yields with excellent enantiomeric excesses (Scheme 5-13).

Scheme 5-15 \(\beta\)-Isocupreidine 82 catalysed aza-BH reaction of dpp-imines with HFIPA.\textsuperscript{104}
From the work of Shi, Adolfsson and Balan, and Hatakeyama, it follows that both the rigid structure of the β-isocupreidine and the phenolic OH group are essential for a high degree of asymmetric induction and sufficient reactivity. Overall, the nucleophilic nitrogen atom in the quinuclidine moiety of acts as a Lewis base to initiate the asymmetric aza-BH reaction, whereas the phenolic hydroxyl group acts as a Lewis acid to stabilise and organise the enolate intermediate and also to promote the subsequent aldol addition.

For the protected imines employed, it turned out that only those imines that have a nitrogen atom attached to electron withdrawing groups were electrophilic enough to participate in the aza-BH reaction.

Recently, modified β-isocupreidine catalysts were reported by Zhu et al. In these catalysts the 6'-OH moiety was replaced by various amide or thiourea functions. Excellent yields and enantioselectivities were obtained with the modified catalyst in the aza-BH reaction of PMPSO₂-protected imines with 2-naphthyl acrylate (Scheme 5-16).

The group of Sasai developed a chiral tertiary amine derived from BINOL. Like β-isocupreidine, this base contains both a subunit possessing a Lewis basic character and two hydroxyl groups exhibiting Lewis acid properties. This ensures the stabilisation of the zwitterionic intermediates. The reaction yields and enantioselectivities were good, albeit with rather long reaction times (Scheme 5-17).

---

**Scheme 5-16** Use of the β-isocupreidine derived bifunctional catalyst in the aza-BH reaction.

**Scheme 5-17** Enantioselective aza-BH reaction catalysed by the BINOL-based tertiary amine.
Chiral Nucleophiles - Phosphines. Starting in 2003, *Shi et al.*\textsuperscript{107} explored the use of chiral phosphines to induce enantioselectivity in the aza-BH reaction. A chiral phosphine derived from BINAP 85 was investigated in the reaction of Ts-imines with methyl vinyl ketone. Good yields and moderate enantioselectivities were achieved, although long reaction times were required. However, poor yields and enantiomeric excesses were obtained with acrylates as substrates (Scheme 5-18).

![Scheme 5-18](image)

Since then, numerous new chiral phosphines have been designed and screened to further improve these pioneering results. Some representative chiral phosphine catalysts evolved from 85 are shown in Table 5-1. These catalysts were employed in the aza-BH reaction of Ts-protected imines with methyl vinyl ketones as Michael acceptors.

**Table 5-1** Enantioselective aza-BH reaction of Ts-imines with methyl vinyl ketone catalysed by chiral phosphines.\textsuperscript{108-111}

A slight modification of the phosphine 85 by replacement of one phenyl group with an alkyl chain led to a dramatic reduction of the reaction time. The best results were obtained with phosphine 86, bearing a n-butyl group. However, in most cases, lower enantioselectivities were observed (Table 5-1, Entry 1). The group of Shi has developed a new chiral phosphine 87 comprising several hydroxy groups. These types of catalysts ensure a better stabilization of the zwitterionic intermediate by creating more hydrogen bonding interactions. Employing phosphine 87 as chiral catalyst in the aza-BH reaction resulted in improved enantiomeric excesses and good yields (Table 5-1, Entry 2). Further improvements in this family of catalysts have been made by Ito et al. Replacing the binaphthol unit of 87 by a phenol led to the organocatalyst 88 with improved catalytic properties, both in terms of yields and enantiomeric excesses (Table 5-1, Entry 3).

Because of the hydrogen bond donating properties of amide groups or thioureas, the group of Shi incorporated these functionalities into chiral phosphine ligands. However, the phosphine-thiourea catalyst 89 as well as the phosphine-amide catalyst 90 led only to moderate enantioselectivities but good yields were obtained (Table 5-1, Entry 4,5). The sterically more demanding phosphine-amide bifunctional catalyst 91 gave similar results as organocatalyst 90 (Table 5-1, Entry 6).

In summary, the chiral phosphine catalyst 87 showed the best results when used in the aza-BH reaction of Ts-protected imines with ketones. However, up to now acrylates remain challenging substrates for chiral phosphine catalysts.

**Chiral Nucleophiles - Sulfides.** Aggarwal et al. have applied the chiral sulfide 92 in the aza-BH-reaction between in situ generated iminium ions and various α,β-unsaturated ketones. While cyclic enones provided the adducts with good yields and enantioselectivities, the latter were very poor when acyclic enones were used (Scheme 5-19).

![Scheme 5-19](image-url)
Chiral Nucleophiles - Carbenes. Recently, Ye et al.\textsuperscript{112} demonstrated that chiral $N$-heterocyclic carbone precursors with a proximal hydroxy group can act as catalysts in aza-BH reactions of cyclopentenone with a Ts-protected imine. The corresponding aza-BH adduct was obtained in good yields but only moderate enantioselectivity (Scheme 5-20).

\text{Ph} & \quad \text{NHTs}
\end{align*} \]

Scheme 5-20 First asymmetric aza-BH reaction with chiral $N$-heterocyclic carbone precursors.\textsuperscript{112}

Chiral Additives - Thioureas. Jacobsen et al.\textsuperscript{83} have developed highly enantioselective catalytic aza-BH reactions between nosylimines and methyl acrylate in the presence of the chiral thiourea derivative 95 and DABCO as nucleophile (Scheme 5-21). Good enantioselectivities but only moderate yields were obtained.

\end{align*} \]

Scheme 5-21 Enantioselective aza-BH reaction catalyzed by chiral thiourea derivative 95.

Chiral Solvent - Ionic Liquids. Besides chiral catalysts, chiral reaction media can also induce high asymmetric induction. Leitner et al.\textsuperscript{113} performed reactions in the chiral ionic liquid methyltrioctylammonium dimalatoborate 96. In the aza-BH reaction between methyl vinyl ketone and tosylimines, good enantioselectivities but only moderate conversions were observed (Scheme 5-22).

5.1.4 Use of Aza-Baylis-Hillman Adducts in Synthesis

The aza-Baylis-Hillman reaction has gained considerable interest because it leads to highly functionalised products.\textsuperscript{114} The synthetic utility of the aza-BH adducts is illustrated in the variety of transformations shown in Scheme 5-23.

Various transformations of Ns-protected $\alpha$-methylene-$\beta$-amino esters to new $\beta$-amino esters have been described by Jacobsen et al..\textsuperscript{83} These transformations include [3+2] cycloadditions of aldoximines (Scheme 5-23, (b)), conjugate additions of 1,3-dicarbonyl compounds (Scheme 5-23, (e)), epoxidations (Scheme 5-23, (g)), and dihydroxylations (Scheme 5-23, (h)).

In particular, the synthesis of new $\beta$-amino ester analogues by hydrogenation of type-B $\beta$-amino esters have been intensively investigated by several research groups.\textsuperscript{115} For example, Brown et al.\textsuperscript{115a} have studied the hydrogenation of $N$-Boc-$\alpha$-methylene-$\beta$-amino esters. The reaction was performed in the presence of a chiral phosphine and
resulted in the kinetic resolution of the starting material, which was recovered with high enantiomeric excess (Scheme 5-23, (c)).

Another transformation of aza-BH adducts is the conversion to pyrrolidines, pyrrolines and pyrroles.\(^{89,116}\) For example, Lamaty et al.\(^{89}\) concentrated on the synthesis of SES-protected pyrrolidines using ring closing metathesis as a key step (Scheme 5-23, (a)). Kim et al.\(^{116d}\) have recently synthesised polysubstituted pyrroles from \(\beta\)-amino-carbonyl compounds (Scheme 5-23, (i)).

The syntheses of piperidines, tetrahydropiperidines and pyridines starting from aza-BH adducts were described by several groups.\(^{94,117}\) For example, Kim et al.\(^{117c}\) transformed suitably substituted \(\beta\)-amino esters to tetrahydropyridines by an intramolecular Heck reaction using a solvent mixture of PEG and DMF (Scheme 5-23, (d)).

The syntheses of \(\beta\)-amino alcohols by reduction of the corresponding aza-BH adducts with LiAlH\(_4\) was published by Shi et al.\(^{118}\) (Scheme 5-23, (j)).

\(\beta\)-Lactams are accessible from aza-BH adducts as illustrated by Hatakeyama et al.\(^{119}\)

The synthesis of \(\beta\)-lactams was carried out from dpp-protected \(\beta\)-amino esters following a deprotonation-cyclisation two step procedure (Scheme 5-23, (f)).

### 5.2 Concept

The application of acrylates as olefinic component in the aza-BH reaction yields enantio-enriched unsaturated \(\beta\)-amino acid esters, which have gained considerable interest due to their important biological properties, their occurrence in natural products and as potential precursors for \(\beta\)-lactams.\(^9\) The most common approach for the synthesis of \(\beta\)-amino acid esters \textit{via} aza-BH reactions is the use of Ts-protected imines and chiral Lewis bases as catalysts.\(^{84}\) However, harsh conditions are required to cleave the Ts-protecting group (see 5.1.2 Substrate Diversity, p. 110). Therefore, the dpp-protecting group should be employed as it activates the imine and can be removed under mild conditions. Furthermore, using dpp-protected imines in combination with various acrylates provide a direct access to \(\beta\)-amino acids by simultaneous removal of the dpp-protecting group and hydrolysis of the ester function (Scheme 5-24, p. 121).\(^{104}\)
Scheme 5-24 According to Hatakeyama,\textsuperscript{104} hydrolytic \(C,N\)-terminal deprotection provides direct access to enantio-enriched \(\alpha\)-methylene-\(\beta\)-amino acids.

For the aza-BH reaction between dpp-protected imines and less activated acrylates a literature survey revealed that the use of chiral Lewis bases only provides moderate enantioselectivities. Alternatively, dpp-protected imines can be activated by \(Zn-(R,R)\)-linked-BINOL complexes as shown by Shibasaki in asymmetric Mannich-type reactions (Scheme 5-25).\textsuperscript{120}

Scheme 5-25 Asymmetric Mannich–type reactions catalysed by a Zn-BINOL complex.

However, so far no example of an enantioselective protocol with chiral metal Lewis acid catalysts is known for the aza-BH reaction.\textsuperscript{121} The following section describes the first applications of non-chiral metal Lewis acids in (aza)-BH reactions:

Adolfsson observed that the \textit{in situ} aza-BH reaction can be accelerated by \(La(OTf)_3\) (Scheme 5-26).\textsuperscript{90a}

Scheme 5-26 \textit{In situ} aza-BH reaction accelerated by \(La(OTf)_3\) according to Adolfsson.\textsuperscript{90a}

Unfortunately, the combination of Lewis acids and tertiary amines in MBH reactions causes the formation of amine-Lewis acid complexes. In these adducts, the \(N\)-nucleophile is not catalytically active. Therefore, in the classic MBH reaction, Aggarwal made use of triethanolamine to liberate the lanthanum-coordinated DABCO, which can then act as a nucleophile (Scheme 5-28, p. 122). In addition, the use of oxygen-rich ligands leads to more Lewis acidic metal complexes and therefore to a rate acceleration of the MBH reaction.\textsuperscript{122}
La(OTf)_(x) (DABCO)_(2) \xrightarrow{N(C_2H_4OH)_3} \text{La(OTf)_(y) (N(C_2H_4OH)_3)_(2)}

Scheme 5-27 DABCO-lanthanum, triethanolamine-lanthanum equilibrium.\(^{122}\)

Furthermore, Sasai et al. successfully employed La-BINOL-derived heterobimetallic complexes in the MBH reaction (Scheme 5-29).\(^{121b}\)

Based on these results, BINOL-based lanthanum complexes should be tested as potential chiral catalysts for aza-Baylis-Hillman reactions of dpp-protected imines.

Shi et al. performed a screening of different nucleophiles for the aza-BH reaction of dpp-protected imine 98a with methyl acrylate 99a and obtained the highest yields when Ph₂PMe is employed (Table 5-2, entry 2 and 4, p. 123).\(^{123}\) However, using Ph₂PMe in a preliminary screening in combination with (R)-LLB (La-Li-(R)-BINOL) resulted in poor enantioselectivities, while the less reactive DABCO provided much higher enantioselectivities (Table 5-2, entries 1 and 3, p. 123).
Table 5-2 Preliminary screening for the best nucleophile in the aza-BH reaction of dpp-imine 98a.\(^a\)

\[
\begin{array}{cccc}
\text{entry} & \text{nucleophile} & (R)-LLB & \text{yield} (\%)^b \quad \text{ee} (\%)^c \\
1 & \text{DABCO} & 10 \text{ mol\%} & 30 & 75 \\
2 & \text{DABCO} & - & 7^d & - \\
3 & \text{Ph}_2\text{PMe} & 10 \text{ mol\%} & 33 & 5 \\
4 & \text{Ph}_2\text{PMe} & - & 29^d & - \\
\end{array}
\]

\(^a\) Reactions were carried out at r.t. in THF (1.0 M) using imine 98a (1.0 eq), acrylate 99a (2.0 eq), DABCO/Ph\(_2\)PMe (20 mol\%), (R)-LLB (10 mol\%). \(^b\) Isolated yield. \(^c\) Determined by HPLC. \(^d\) Yields are in agreement with literature values.\(^{123}\)

In conclusion, dpp-protected imines combined with various acrylates and DABCO as nucleophile should be employed as test system for the screening of Lewis acidic BINOL-based lanthanum complexes.

5.3 Results & Discussion

For the application of chiral Lewis acid complexes in the aza-Baylis-Hillman reaction, an initial ligand screening was performed using La(O\(_i\)Pr\(_3\)) and various (\(R\))-BINOL-based ligands in the reaction of dpp-protected benzaldimine 98a and methyl acrylate 99a as test system (Table 5-3, p. 124).\(^v\) Using ligand 101 ((\(R\))-BINOL), the corresponding aza-Baylis-Hillman adduct was obtained in 25 % yield and 70 % ee (Table 5-3, entry 1). Increasing the ligand to metal ratio from 1:1 to 2:1 yielded the same result (Table 5-3, entry 2). Sterically more demanding groups in the BINOL 3,3’-positions, i.e. 2-naphthyl 102, 8-anthracenyl 103, as well as 3,5-bis-CF\(_3\)- and 2,4,6-tri-\(i\)Pr-substituted phenyl groups 104 and 105 decreased the yields and enantioselectivities (Table 5-3, entries 3-6 and 9-12). In contrast, a high enantioselectivity of 89 % ee was achieved with linked-(\(R\),\(R\))-BINOL 97 (Table 5-3, entry 7). Since increasing the ligand to metal ratio for (\(R\))-BINOL 101 gave no improvement (Table 5-3, entry 2), it is postulated that the increase in enantioselectivity for linked-(\(R\),\(R\))-BINOL 97 complex was due to its higher stability as compared to the La-(\(R\))-BINOL complex.\(^{124}\) Similar reactivity and selectivity patterns

\(^v\) Absolute product configuration was rigorously established for the aza-BH adducts 100aa and 100ae by comparison of the HPLC elution profiles with those reported by Hatakeyama.\(^{104}\) For all other aza-BH products, absolute configuration is drawn in analogy.
were observed by replacing methyl acrylate with phenyl acrylate (Table 5-3, entry 9-14).

\textsuperscript{a} Reactions were carried out at r.t. in THF (1.0 M) using imine 98\textsuperscript{a} (1.0 eq), acrylate 99\textsuperscript{a,b} (2.0 eq), DABCO (20 mol%), La(O\textsubscript{i}Pr)\textsubscript{3} (10 mol%), and (R)-BINOL based ligand 97, 101-105 (10 mol\%). \textsuperscript{b} Isolated yield. \textsuperscript{c} Determined by HPLC. \textsuperscript{d} 20 mol\% ligand. \textsuperscript{e} Catalyst loading: 20 mol\% La(O\textsubscript{i}Pr)\textsubscript{3}-ligand.

The La-linked-(R,R)-BINOL complex is well known for its dual reactivity as Lewis acid and Brønsted base. The basicity of the catalyst was increased by deprotonation with KHMDS, NaHMDS or n-BuLi. However, applying these heterobimetallic complexes in the aza-Baylis-Hillman reaction did not result in higher yields or enantioselectivities (Table 5-4, entries 2-4, p. 125) relative to the non-metallated species.
To vary the catalyst’s Lewis acidity, linked-(R,R)-BINOL 97 was coordinated to several M(OiPr)₃. The activity and selectivity of the resulting complexes were compared to the corresponding La-linked-(R,R)-BINOL complex. The Sm- and Y-complexes showed similar reactivity and selectivity patterns (Table 5-5, entries 2,3). In contrast, the more Lewis-acidic Ti(iPrO)₄ did not lead to a catalytically active complex (Table 5-5, entry 4). The increased basicity of the Sr-complex led to poor yields and enantioselectivities (Table 5-5, entries 5,6). In the absence of M(OiPr)₃, ligand 97 did not show any catalytic activity (Table 5-5, entry 7).

⁹ Reactions were carried out at r.t. in THF (1.0 M) using imine 98a (1.0 eq), methyl acrylate 99a (2.0 eq), DABCO (20 mol%), La(OTf)₃ (10 mol%) and ligand 97 (10 mol%). b Isolated yield. c Determined by HPLC. e The opposite enantiomer was formed in excess.
To further optimise the reaction conditions, a test system consisting of the La-linked-(R,R)-BINOL complex as catalyst in combination with dpp-protected benzaldimine 98a and methyl acrylate 99a as substrates was employed. Among the three solvents tested, the best yield was achieved in MeCN (Table 5-6, entry 2), while the highest enantioselectivity was observed in THF (Table 5-6, entry 3). Higher yields were obtained in THF upon increasing the substrate concentration, without affecting the ee values (Table 5-6, entry 4). No improvements were observed with higher DABCO loadings or addition of molecular sieves (Table 5-6, entries 5 and 6). Increased yields resulted from higher amounts of methyl acrylate 99a (Table 5-6, entry 7). Raising the temperature from r.t. to 40 °C only led to a slight increase in yield due to the increased formation of byproducts as well, while the enantioselectivity was not adversely affected (Table 5-6, entry 8). These conditions could not be applied to phenyl acrylate 99b, due to its limited solubility in THF. Instead, the best reaction conditions were found to be a 1 M solution of the imine 98a in THF, using 2 eq of the acrylate 99b (Table 5-6, entry 9).

*Reactions were carried out at r.t. in THF using imine 98a (1.0 eq), acrylate 99a,b, DABCO (20 mol%), La(OTf)$_3$ (10 mol%) and ligand 97 (10 mol%). *Isolated yield. *Determined by HPLC. *Molecular sieves added (200mg/mmol). *40 mol% DABCO, *Reaction performed at 40 °C.

Among the acrylates tested in a substrate screening, the highest yields were achieved using the very reactive phenyl acrylate 99b and 2-naphthyl acrylate 99d (Table 5-7, entries 2,8 and 4,10, p. 127). Employing the even more reactive 1,1,1,3,3,3-hexafluoroisopropyl acrylate 99e led to reduced yields, due to the increased formation of bypro-
Employing methyl acrylate 99a led to the highest enantioselectivities (Table 5-7, entries 1 and 7). Acrylonitrile 99f gave only racemic products, due to its fast background reaction (Table 5-7, entry 6). Applying the dpp-protected para-Cl-substituted benzaldimine derivative 99b instead of the dpp-protected benzaldimine 98a led in most cases to higher enantioselectivities at virtually unchanged yields (Table 5-7, entries 7-11 vs. 1-6). Aliphatic imines were also tested, but only provided traces of the corresponding aza-BH adducts.

Reactions were carried out at r.t. in THF (1.0 M) using imine 98a,b (1.0 eq), olefin component 99a-f (2.0 eq), DABCO (20 mol%), La(OTf)₃ (10 mol%) and ligand 97 (10 mol%). Isolated yield, determined by HPLC. The opposite enantiomer was formed in excess.

Acidic hydrolysis of the aza-Baylis-Hillman products 100 provides a single step access to the β-amino acids (Scheme 5-30, p. 128). The viability of this approach to α-methylene-β-amino acids 106 was proven by the hydrolysis of the aza-Baylis-Hillman adducts 100: After refluxing in 20 % aqueous HCl for 6 h, the corresponding β-amino acids 106 were isolated in up to 75 % yield.

Therefore, Hatakeyama performed aza-BH reactions with 1,1,1,3,3,3-hexafluoroisopropyl acrylate 99e in DMF at -55 °C. Unfortunately, these reaction conditions could not be applied for the La-linked-BINOL catalysed aza-BH reaction due to solubility problems.
In conclusion, it has been shown for the first time that the aza-Baylis-Hillman reaction can be catalysed enantioselectively by a chiral Lewis acidic metal complex. Using the La-linked-\((R,R)\)-BINOL complex as catalyst and dpp-protected imines as substrates the corresponding aza-BH adducts could be obtained in up to 68 % yield and up to 90 % ee. Hydrolytic deprotection of the highly enantio-enriched aza-Baylis-Hillman products thus obtained grants access to \(\alpha\)-methylene-\(\beta\)-aminoacids.

5.4 Outlook

In this work, it was shown for the first time that the aza-Baylis-Hillman reaction can be catalysed with chiral Lewis acidic complexes. Based on these studies, many different Lewis acidic metal complexes, which are known to activate protected imines, should be also tested in a future work. For example, the chiral heterobimetallic Cu/Sm/Schiff base/OAr complex 107, which has been successfully employed in the asymmetric nitro-Mannich reaction for the activation of Boc-protected imines might also be used in the aza-BH reaction (Scheme 5-31).\(^{126}\)

![Scheme 5-31 Proposed asymmetric aza-BH reaction with N-Boc-protected imines catalysed by the chiral heterobimetallic complex 107.](image-url)

To further optimise the results of the present work, two main goals should drive future researches: (a) simplifying the procedure and (b) improving the yields.

(a) According to Shi, it is possible to synthesise the imine electrophile \textit{in situ} in the aza-BH reaction from the corresponding aldehyde and diphenylphosphine amide.\(^{88}\) This
en anna!oselective azaBH Reaction Catalysed by a La-linked-BINOL Complex

**in situ** protocol should be applied to the system developed in the present thesis (Scheme 5-32).

\[
\text{Ar}_2\text{H} + \text{dpp-NH}_2 + \text{OR} \xrightarrow{\text{**DABCO**}} \frac{\text{La(OiPr)}_3\text{-ligand 97}}{\text{solvent, r.t., 35 h}} \text{Ar}_2\text{NH} + \text{dpp-NH}_2 + \text{OR}
\]

**Scheme 5-32** Proposed asymmetric **in situ** aza-BH reaction catalysed by the La-linked-(R,R)-BINOL complex.

(b) According to previous studies, the low yields observed when employing DABCO as catalyst could be improved by replacement with a more reactive phosphine. However, in combination with the La-linked-(R,R)-BINOL complex, Ph\textsubscript{2}PMe led to lower enantioselectivities than DABCO. This low selectivity might be due to a fast background reaction (see Table 5-2, p. 123).

An intramolecular combination of Ph\textsubscript{2}PMe and the La-linked-(R,R)-BINOL complex might solve this problem and might increase the yield while maintaining high enantioselectivities (Scheme 5-33).

\[
\text{O} \quad \text{La} \quad \text{O} \quad \text{Ph}_2\text{P}
\]

**Scheme 5-33** Complex derived from La(OiPr\textsubscript{3}) and a linked-(R,R)-BINOL-diphenylphosphine derivative.

A further improvement could be the substitution of the diphenylphosphino group by the dimethylphosphino group (Scheme 5-34). As shown by Shi, the chiral dimethylphosphino-derived catalyst exhibits much higher reactivity in the aza-BH reaction than its corresponding diphenyl analogue.\textsuperscript{127}

\[
\text{O} \quad \text{La} \quad \text{O} \quad \text{Me}_2\text{P}
\]

**Scheme 5-34** Complex derived from La(OiPr\textsubscript{3}) and a linked-(R,R)-BINOL-dimethylphosphine derivative.
However, La-coordination by the phosphine might decrease its nucleophilicity. Therefore, designing a chiral ligand with the dimethylphosphine moiety in the 3-position and a La-coordinating hydroxy group in the 2-position might lead to a highly reactive and highly selective bifunctional catalyst (Scheme 5-35).

Scheme 5-35 La-linked-(R,R)-BINOL complex with non La-coordinated dimethylphosphine group.

5.5 Experimental Part

5.5.1 General Experimental Conditions

Preparative thin layer chromatography was performed with Merck F-254 TLC plates. Flash chromatography was performed on silica gel (Macherey-Nagel MN-Kieselgel 60, 230-240 mesh). Analytical TLC was performed on aluminium backed silica plates (Macherey-Nagel, Polygram© SIL G/UV254), detection by using UV fluorescence. Melting points were determined on a Büchi melting point apparatus and are uncorrected. $^1$H-NMR spectra were recorded at 500 MHz on a JEOL JNM-LA500 spectrometer and at 300 MHz on Bruker AC 300 and DPX 300 instruments, respectively; $^{13}$C NMR spectra at 75.5 MHz on a Bruker DPX 300. Chemical shifts (δ) are given in parts per million (ppm) referenced to TMS. For the fine-structure interpretation the abbreviations of the signals are the following: s = singulet, d = doublet, t = triplet, q = quartet, m = multiplet. HPLC analyses were performed using an Agilent 1100 Series or a JASCO HPLC system. High resolution mass spectra (HR ESI-MS) were recorded on a Finnigan MAT 900 ST spectrometer. Infrared spectra were recorded on a Perkin-Elmer Paragon 1000 FT-IR spectrometer using ATR technique. All commercially available chemicals were used without further purification. Anhydrous solvents were distilled from appropriate drying agents prior to use.

All experiments are characterised by a number within the bracket: [XX-SEE-XXX]. The roman number in front of the three-letter-code indicates the volume number of the
laboratory notebook, whereas the number after the three-letter-code indicates the experiment number in the corresponding notebook volume.

5.5.2 Syntheses of the Substrates for the Aza-BH Reaction

5.5.2.1 Synthesis of $P,P$-Diphenylphosphinic amide (109)$^{128}$

[IV-SEE-300]

A solution of diphenylphosphinic chloride 108 (20.0 g, 84.5 mmol, 1.00 eq) in dry CH$_2$Cl$_2$ (40 ml) was added dropwise with stirring to a saturated ethanolic ammonia solution (170 ml) and CH$_2$Cl$_2$ (70 ml) at -20 °C. The reaction mixture was stirred for 12 h at r.t.. The precipitated solid was filtered off and the solvents were removed under reduced pressure. The residue was dissolved in CHCl$_3$ (240 ml) and washed with 5 % aqueous K$_2$CO$_3$ (3 x 50 ml) and distilled water (70 ml). The organic layer was separated, dried over MgSO$_4$, and the solvent was removed under reduced pressure. The residue was recrystallised from toluene to yield 16.6 g (76.0 mmol, 90 %) of $P,P$-diphenylphosphinic amide 109 as an off-white solid.

C$_{12}$H$_{12}$NOP (217.2 g/mol)

m.p. 163-164 °C  [m.p. ref.$^{128}$: 164-166 °C]

$^1$H NMR (300 MHz, CDCl$_3$): $\delta$ [ppm] = 7.93-7.86 (m; 4H), 7.50-7.37 (m; 6H), 3.53 (s; 2H).

$^{13}$C NMR (75.5 MHz, CDCl$_3$): $\delta$ [ppm] = 134.5, 132.7, 131.9, 131.8, 128.5, 128.4.

### 5.5.3 Syntheses of Racemic Reference Substances

#### 5.5.3.1 Synthesis of Methyl ($\beta$S)-$\beta$-[(diphenylphosphinoyl)amino]-$\alpha$-methylenebenzene-propanoate (rac-100aa)

[IV-SEE-336]

Under argon atmosphere, methyl acrylate 99a (70.8 µl, 67.6 mg, 786 µmol, 1.20 eq) was added to a mixture of imine 98a (200 mg, 655 µmol, 1.00 eq) and diphenylmethylphosphine (24.3 µl, 26.2 mg, 131 µmol, 20.0 mol%) in dry THF (1 ml). The suspension was stirred for 72 h at r.t.. The solvent and excess acrylate were removed under reduced pressure. The residue was purified by preparative-TLC ($c$-hexane/EtOAc 3:1) to obtain 90.0 mg (229 µmol, 35 %) of methyl ($\beta$S)-$\beta$-[(diphenylphosphinoyl)amino]-$\alpha$-methylenebenzene-propanoate rac-100aa as colourless solid.

The spectroscopical data are in agreement with the data in chapter 5.5.4, p.144 et sqq..
5.5.3.2 Synthesis of Phenyl (βS)-β-[(diphenylphosphinoyl)amino]-α-methylenebenzene-propanoate (rac-100ab)

Under argon atmosphere, phenyl acrylate 99b (544 µl, 582 mg, 3.93 mmol, 1.20 eq) was added to a mixture of imine 98a (1.00 g, 3.26 mmol, 1.00 eq) and triphenylphosphine (206 mg, 786 µmol, 20.0 mol%) in dry THF (3 ml). The suspension was stirred for 72 h at r.t. The solvent and excess acrylate were removed under reduced pressure. The residue was purified by column chromatography (c-hexane/EtOAc 3:1) to obtain 740 mg (1.63 mmol, 50 %) of phenyl (βS)-β-[(diphenylphosphinoyl)amino]-α-methylenebenzenepropanoate rac-100ab as colourless solid.

The spectroscopical data are in agreement with the data in chapter 5.5.4, p.144 et sqq.
5.5.3.3 Synthesis of 1,1-Dimethylethyl (βS)-β-[(diphenylphosphinoyl)amino]-α-methylenebenzenepropanoate (rac-100ac)

Under argon atmosphere, tert-butyl acrylate 99c (580 µl, 512 mg, 4.00 mmol, 4.00 eq) was added to a mixture of imine 98a (305 mg, 1.00 mmol, 1.00 eq) and diphenylmethylphosphine (37.0 µl, 40.0 mg, 200 µmol, 20.0 mol%) in dry THF (1 ml). The suspension was stirred for 72 h at r.t.. The solvent and excess acrylate were removed under reduced pressure. The residue was purified by preparative-TLC (c-hexane/EtOAc 3:1) to obtain 130 mg (300 µmol, 30 %) of 1,1-dimethylethyl (βS)-β-[(diphenylphosphinoyl)amino]-α-methylenebenzenepropanoate rac-100ac as colourless solid.

The spectroscopical data are in agreement with the data in chapter 5.5.4, p.144 et sqq.
5.5.3.4 Synthesis of (βS)-β-[(Diphenylphosphinoyl)amino]-α-methylenebenzenepropanenitrile (rac-100af)

Under argon atmosphere, acrylonitrile 99af (99.5 µl, 79.6 mg, 1.50 mmol, 1.50 eq) was added to a mixture of imine 98a (305 mg, 1.00 mmol, 1.00 eq) and 1,4-diazabicyclo-[2.2.2]octane (16.8 mg, 150 µmol, 15.0 mol%) in dry MeCN (1 ml). The suspension was stirred for 72 h at r.t.. The solvent and excess acrylate were removed under reduced pressure. The residue was purified by preparative-TLC (c-hexane/EtOAc 3:1) to obtain 230 mg (642 µmol, 64 %) of (βS)-β-[(diphenylphosphinoyl)amino]-α-methylenebenzenepropanenitrile rac-100af as colourless solid.

The spectroscopical data are in agreement with the data in chapter 5.5.4, p.144 et sqq..
5.5.3.5 Synthesis of Methyl (βS)-4-chloro-β-[(diphenylphosphinoyl)amino]-α-methylenebenzenepropanoate (rac-100ba)

Under argon atmosphere, methyl acrylate 99a (360 µl, 344 mg, 4.00 mmol, 4.00 eq) was added to a mixture of imine 98b (339 mg, 1.00 mmol, 1.00 eq) and diphenylmethylphosphine (37.0 µl, 40.0 mg, 200 µmol, 20.0 mol%) in dry CH₂Cl₂ (1 ml). The suspension was stirred for 72 h at r.t.. The solvent and excess acrylate were removed under reduced pressure. The residue was purified by preparative-TLC (c-hexane/EtOAc 3:1) to obtain 200 mg (470 µmol, 47 %) of methyl (βS)-4-chloro-β-[(diphenylphosphinoyl)-amino]-α-methylenebenzenepropanoate rac-100ba as colourless solid.

The spectroscopical data are in agreement with the data in chapter 5.5.4, p.144 et sqq..
5.5.3.6 Synthesis of Phenyl (βS)-4-chloro-β-[(diphenylphosphinoyl)amino]-α-methylenebenzenepropanoate (rac-100bb)

[IV-SEE-328]

\[
\text{98b} \quad \text{99b} \quad \text{rac-100bb}
\]

Under argon atmosphere, phenyl acrylate 99b (345 µl, 370 mg, 2.50 mmol, 2.50 eq) was added to a mixture of imine 98b (339 mg, 1.00 mmol, 1.00 eq) and triphenylphosphine (39.3 mg, 150 µmol, 15.0 mol%) in dry THF (1 ml). The suspension was stirred for 72 h at r.t.. The solvent and excess acrylate were removed under reduced pressure. The residue was purified by preparative-TLC (c-hexane/EtOAc 3:1) to obtain 241 mg (510 µmol, 51 %) of phenyl (βS)-4-chloro-β-[(diphenylphosphinoyl)amino]-α-methylenebenzenepropanoate rac-100bb as colourless solid.

The spectroscopical data are in agreement with the data in chapter 5.5.4, p.144 et sqq..
5.5.3.7 *Synthesis of 1,1-Dimethylethyl (βS)-4-chloro-β-[(diphenylphosphinoyl)amino]-α-methylenebenzenepropanoate (rac-100bc)*

[IV-SEE-316]

![Chemical Structures](image)

Under argon atmosphere, *tert*-butyl acrylate 99c (580 µl, 512 mg, 4.00 mmol, 4.00 eq) was added to a mixture of imine 98b (339 mg, 1.00 mmol, 1.00 eq) and diphenylmethylphosphine (37.0 µl, 40.0 mg, 200 µmol, 20.0 mol%) in dry CH₂Cl₂ (1 ml). The suspension was stirred for 72 h at r.t.. The solvent and excess acrylate were removed under reduced pressure. The residue was purified by preparative-TLC (c-hexane/EtOAc 3:1) to obtain 160 mg (342 µmol, 34 %) of 1,1-dimethylethyl (βS)-4-chloro-β-[(diphenylphosphinoyl)amino]-α-methylenebenzenepropanoate rac-100bc as colourless solid.

The spectroscopical data are in agreement with the data in chapter 5.5.4, p.144 et sqq..
5.5.3.8 Synthesis of (βS)-4-Chloro-β-[(diphenylphosphinoyl)amino]-α-methylenebenzenepropanenitrile (100bf)

Under argon atmosphere, acrylonitrile 99f (99.5 µl, 79.6 mg, 1.50 mmol, 1.50 eq) was added to a mixture of imine 98b (339 mg, 1.00 mmol, 1.00 eq) and 1,4-diazabicyclo-[2.2.2]octane (22.4 mg, 200 µmol, 20.0 mol%) in dry MeCN (1 ml). The suspension was stirred for 72 h at r.t. The solvent and excess acrylate were removed under reduced pressure. The residue was purified by preparative-TLC (c-hexane/EtOAc 3:1) to obtain 200 mg (509 µmol, 51 %) of (βS)-4-chloro-β-[(diphenylphosphinoyl)amino]-α-methylenebenzenepropanenitrile rac-100bf as colourless solid.

The spectroscopical data are in agreement with the data in chapter 5.5.4, p.144 et sqq.
5.5.4 General Procedure for the (R,R)-La-Linked BINOL Catalysed Aza-Baylis-Hillman Reaction of N-Diphenylphosphinoyl-Protected Imines with Olefins

![Chemical Structures](image)

A 0.2 M solution of La(OiPr)$_3$ in THF (150 µl, 30.0 µmol, 10.0 mol%) was added to linked-(R,R)-BINOL 97 (18.4 mg, 30.0 µmol, 10.0 mol%) at 0 °C. After stirring for 15 min at 0 °C and 2 h at r.t., the iPrOH and THF were removed under reduced pressure. DABCO (6.73 mg, 60.0 µmol, 20.0 mol%) and the imine 98 (300 µmol, 1.0 eq) were added. The solids were dissolved in THF (300 µl), and the olefin component 99 (600 µmol, 2.00 eq) was added. After 35 h, the solvent and excess acrylate were removed under reduced pressure and the crude mixture was purified by preparative thin layer chromatography. The enantiomeric excess was determined by HPLC analysis using a chiral column.

5.5.4.1 Methyl (βS)-β-[(diphenylphosphinoyl)amino]-α-methylenebenzenepropanoate (100aa)

Compound 100aa was obtained as a colourless solid from 98a and 99a in 34 % yield. The enantiomeric purity was determined to be 89 % ee by HPLC (Chiralpak AD-H, 90:10 iPrOH/n-hexane, 1.0 ml/min; τ$_R$ = 38.7 min (S), 42.8 min (R)).

C$_{23}$H$_{22}$NO$_3$P (391.2 g/mol)

HR ESI-MS calcd for C$_{32}$H$_{25}$ClNO$_3$P $[\text{M+Na}]^{+}$: 560.1159, found: 560.115.

5.5.4.11 (βS)-4-Chloro-β-[(diphenylphosphinoyl)amino]-α-methylenebenzenepropanenitrile (100bf)

Compound 100bf was obtained as a colourless solid from 98b and 99f in 52 % yield. The enantiomeric purity was determined to be 11 % ee by HPLC (Chiralpak AD-H, 90:10 iPrOH/n-hexane, 1.0 ml/min; $\tau_R = 46.8$ min (S), 51.3 min (R)).

C$_{22}$H$_{18}$ClN$_2$OP (392.8 g/mol)

m.p. 142-144 °C [m.p. ref.$^{13}$t: 142-143 °C]

$^1$H NMR (300 MHz, CDCl$_3$): $\delta$ [ppm] = 7.94-7.84 (m; 4H), 7.58-7.44 (m; 6H), 7.37-7.30 (m; 4H), 5.98 (d; $J = 17.8$ Hz, 2H), 4.98 (t; $J = 10.2$ Hz, 1H), 3.66 (dd; $J = 10.2$ Hz, $J = 7.4$ Hz, 1H).

$^{13}$C NMR (75.5 MHz, CDCl$_3$): $\delta$ [ppm] = 137.4, 137.4, 134.6, 132.5, 132.3, 132.2, 132.1, 131.9, 131.5, 130.7, 130.5, 129.3, 128.9, 128.8, 128.7, 128.6, 128.3, 125.4, 125.1, 116.9.

IR (ATR) $\tilde{\nu}$ [cm$^{-1}$] = 3144, 2866, 2218, 1490, 1436, 1183, 1106, 1090, 751, 725.

HR ESI-MS calcd for C$_{22}$H$_{18}$ClN$_2$OP $[\text{M+Na}]^{+}$: 415.0743, found: 415.074.

The spectroscopical data are in agreement with the literature.$^{13}$t
5.5.5 Hydrolytic C,N Terminal Deprotection

5.5.5.1 Synthesis of (βS)-β-Amino-α-methylenebenzenepropionic acid hydrochloride (106a)

[IV-SEE-334]

A mixture of 100ab (300 mg, 661 µmol, 1.00 eq) in 20 % HCl (7 ml) was refluxed for 6 h. The reaction mixture as washed with Et₂O (3 x 4 ml) and EtOAc (2 x 4 ml) and the solvent was evaporated. The residue was dried under vacuo to give amino acid hydrochloride 106a (105 mg, 496 µmol, 75 %) as a colourless solid.

C₁₀H₁₂ClNO₂ (213.6 g/mol)

m.p. 217-219 °C (decomposition)

¹H NMR (300 MHz, D₂O): δ [ppm] = 7.43-7.34 (m; 5H), 6.59 (s; 1H), 5.97 (s; 1H), 5.36 (s; 1H).

The OH- as well as the NH₃⁺- protons could not be detected.

¹³C NMR (75.5 MHz, D₂O): δ [ppm] = 167.9, 136.1, 134.1, 129.9, 129.5, 129.3, 127.3.

IR (ATR) \( \tilde{\nu} \ [\text{cm}^{-1}] = 3385, 2870, 2600, 1962, 1697, 1626, 1577, 1493, 1435, 1395, 1252, 1164, 1116, 1004, 970, 919, 827, 759. \)

HR ESI-MS calcd for C₁₀H₁₂ClNO₂ [M-Cl]⁺: 178.087 , found: 178.0868

The spectroscopical data are in agreement with the literature.
5 Enantioselective aza-BH Reaction Catalysed by a La-linked-BINOL Complex

5.5.5.2 \((\beta S)-4\)-Chloro-\(\beta\)-amino-\(\alpha\)-methylenebenzenepropionic acid hydrochloride \((106b)\)

[IV-SEE-335]

\[
\begin{array}{cc}
\text{100ba} & \text{106b}
\end{array}
\]

A mixture of 100ba (200 mg, 470 \(\mu\)mol, 1.00 eq) in 20 % HCl (5 ml) was refluxed for 6 h. The reaction mixture as washed with Et\(_2\)O (3 x 3 ml) and EtOAc (2 x 3 ml) and the solvent was evaporated. The residue was dried under vacuo to give amino acid hydrochloride 106b (72.0 mg, 291 \(\mu\)mol, 62 %) as a colourless solid.

\[
\begin{array}{c}
\text{100ba} \quad \xrightarrow{20 \% \text{ HCl}} \quad \text{reflux, 6 h} \quad \text{106b, 62 \%}
\end{array}

6.1 Abbreviations

For SI units the generally accepted abbreviations were used.

- **abs.** absolute (distilled and dried)
- **Ac** Acetyl
- **ANF** Atrial natriuretic factor
- **aq.** Aqueous
- **Ar** Aryl
- **ATR** Attenuated total reflection
- **BH** Baylis Hillman
- **BINAP** 2,2'-Bis(diphenylphosphino)-1,1'-binaphthyl
- **BINOL** 1,1'-Binaphthalene-2,2'-diol
- **Boc** tert-butyloxy carbonyl
- **BOP** (Benzotriazol-1-yl oxy)-tris(dimethyl amino)-phosphonium
- **Bu** Butyl
- **Cbz** Carboxybenzyl
- **d** Day(s)
- **DABCO** 1,4-Diazabicyclo[2.2.2]octane
- **DACH** 1,2-Diaminocyclohexane
- **DBU** 1,8-Diazabicyclo[5.4.0]undec-7-en
- **DCE** Dichloroethane
- **DCM** Dichloromethane
- **DIANANE** 2,5-Diamo-bicyclo[2.2.1]heptane
- **DMEM** Dulbecco’s-modified eagle’s medium
- **DMF** N,N-Dimethyl formamide
- **DMSO** Dimethylsulfoxide
- **DNA** Desoxyribonucleic acid
- **DOS** Diversity orientated screening
- **dpp** Diphenyl phosphinoyl
- **EB** Embryoid bodies
- **ECG** Electrocardiogram
- **ee** Enantiomeric excess
- **EGFP** Enhanced green fluorescence protein
- **ent-** Enantiomer
- **eq(uiv)** Equivalent(s)
- **(m)ES** (murine) Embryonic stem
- **Et** Ethyl
- **et sqq.** And the following (et sequentia)
- **EWG** Electron withdrawing group

6.3 Abstract - Kurzzusammenfassung

Abstract
In this work, new substances for the chemical induction of cardiomyogenesis from embryonic stem (ES) cells have been developed and contributions to asymmetric C-C couplings were made.

A transgenic murine ES cell lines was used to investigate the effects of (thio)urea and cinchona-alkaloid derivatives on cardiomyogenesis. Various compound screenings yielded substances which led to a 50 % to 80 % increased cardiomyogenesis compared to untreated cells. In the test system investigated, time dependent screening approaches appeared to be of limited suitability for the identification of potential cellular targets.

A facile two-step procedure for the preparation of Takemoto’s catalyst was developed. The thiourea moiety was obtained by condensation of 3,5-bis(trifluoromethyl)aniline with phenylchlorothioformate and direct reaction with trans-1,2-diaminocyclohexane. Subsequent reductive dimethylation using formaldehyde / zinc afforded Takemoto’s catalyst in an overall yield of 36 %.

For the first time, an enantioselective aza-Baylis-Hillman reaction was catalysed by a chiral Lewis acidic metal complex. N-dpp-α-methylene-β-amino acid esters were obtained in up to 68 % yield and up to 90 % ee, using a La-linked-(R,R)-BINOL complex as catalyst and N-dpp-protected imines as substrates. The subsequent hydrolytic C,N-terminal deprotection provided direct access to enantio-enriched α-methylene-β-amino acids in up to 75 % yield.

Kurzzusammenfassung
In Rahmen dieser Arbeit wurden neue Substanzen für die chemisch induzierte Kardiomyogenese von embryonalen Stammzellen entwickelt und Beiträge zu asymmetrischen C-C Kupplungen geleistet.

6.4 Erklärung

Die Bestimmungen dieser Promotionsordnung sind mir bekannt. Die von mir vorgelegte Dissertation ist von Prof. Dr. A. Berkessel betreut worden."

Köln, 2009-04-28
