Acknowledgement

I want to thank my principal advisor, Prof. Dr Axel Klein, who accepted me into his research group, allowed me to pursue my interest in chemistry, and guided and mentored me so that my interest in chemistry could flourish. His support has been critical throughout the duration of this project. I also want to thank my second supervisor, Prof. Dr Sanjay Mathur, who has consistently shown an interest in my project and whose lab I conducted numerous experiments, including XPS, SEM/EDX measurements and microwave-assisted experiments vital to my project. Special thanks to the DAAD for the Research Grants Award (award number: 91732061), which serves as my financial support during the duration of my project. It is impossible to attempt this project without the funding.

I would like to thank Dr. Silke Kremer and Dr. Jörg Neudörfl at the Department of Chemistry and Biochemistry for single crystal and powder X-ray measurements. I also want to thank the NMR department at the University of Cologne, notably Dr Daniel Friedrich, Dr Philipp Hegemann and Dr Daniela Naumann. I also want to thank Dr. Stefan Roitsch and Mrs. Ruth Bruker at the Department of Electron Microscopy and Electron Spectroscopy for the SEM-TEM and EDX investigation. In addition, I am grateful to Dr. Selina Olthof for the XPS measurement. I would also like to thank my lab colleagues Maryam, Toby, Rick, Hasi, Sascha, Lukas, Josy, Vlad, Leo, Rosy and Johannes. Your warm support during our time in the lab was incredible.

I want to thank my father and mother, Mr and Mrs Anthony for raising me and providing me with all the support I needed. I want to also thank my siblings, George, Kenneth, Dorothy, Stella and Loreter. Finally, I want to thank my wife, Deborah and my boys (Nathaniel and Ethan) for coming into my life. Your support before and during this project is unmeasurable, and it would have been impossible without you and the kids (Nathaniel and Ethan) in my life.

Abstract

Synthesis, Characterization, and Functionalization of Bis-Thiosemicarbazones: Applications In Metal Binding, Catalysis and as Single-Source Precursor

Pentadentate Bis-thiosemicarbazones (BTSC) of class $S^N^N^N^S$ binding sites have been known for their therapeutic activities. Thus, investigation of pentadentate BTSC in other fields besides biological activities is often scarce or lacking. Pentadentate BTSC ligand of type $S^N^N^N^S$ comprises a dicarbonyl backbone, N^S core and a diamine tail. Pentadentate BTSC is appealing because the dicarbonyl backbone and the diamine tail can be derivatized, functionalized and conjugated with a nanoparticle (NP) or other molecules, thus potentially expanding the applications of pentadentate BTSC. Thus, the study commenced with the synthesis of various pentadentate BTSC ligands and their metal complexes to expand the library of BTSC. Single crystal XRD showed that Pd^{2+} and Zn^{2+} conform to a distorted square planar geometry. Pd^{2+} bind through $S^{thiol}^N^{imine}^N^{pyridinic}^N^{amide}$, exhibiting a thione/thiol character. Zn^{2+} is coordinated through $S^{thiol}^N^{imine}^N^{imine}^S^{thiol}$ showing only thiol characters. Cu^{2+} coordinate through $S^{thiol}^N^{imine}^N^{pyridinic}^N^{imine}^S^{thiol}$, resulting in a bipyramidal geometry.

The reaction between pentadentate BTSC and the linkers (dopamine hydrochloride and (3-aminopropyl)-triethoxysilane) was first carried out and to establish a new route to conjugate BTSC with NPs. 1H NMR spectroscopy revealed the new amide bond, confirming the successful conjugation of BTSC with (3-aminopropyl)-triethoxysilane) or dopamine. Magnetic Fe_3O_4 conjugate of BTSC was first synthesized using the well-established NHS/EDC coupling route. The Fe_3O_4 was first coated with SiO_2 , followed by the deposition of (3-aminopropyl)-triethoxysilane to afford amine functionalized Fe_3O_4 ($Fe_3O_4@SiO_2$ -APTES) and subsequent conjugation with BTSC ($Fe_3O_4@SiO_2$ -APTES-BTSC). The magnetic material ($Fe_3O_4@SiO_2$ -APTES-BTSC) exhibit a high adsorption capacity for binding Pd^{2+} . The unusual high uptake of Pd^{2+} was attributed to different adsorbed species contributing to the uptake of Pd^{2+} ions, as revealed by different characterization techniques, including DFT calculations.

The newly developed route was employed to conjugate BTSC with different NP (SiO_2 and Fe_2O_3). SiO_2 was conjugated with BTSC at the dicarbonyl backbone, and Fe_2O_3 was conjugated with BTSC at the diamine tail part of the BTSC. SiO_2 was initially pre-functionalized with (3-aminopropyl)-triethoxysilane, and Fe_2O_3 was pre-functionalized with dopamine, and the subsequent reaction with BTSC at room temperature affords $SiO_2@APTES$ -BTSC or Fe_2O_3 -Dopamine-BTSC. $SiO_2@APTES$ -BTSC was further coordinated with Pd^{2+} ions and employed as a heterogeneous catalyst in the

Suzuki-Miyaura cross-coupling reaction. X-ray Photoelectron Spectroscopy investigation of SiO₂@APTES-BTSC-Pd revealed that palladium is predominantly Pd⁰, thus, an invaluable catalyst for coupling aryl compounds.

Metal complexes of pentadentate BTSC were also used as single-source precursors for synthesizing metal sulfides NPs. The metal sulfide NP particles were obtained by microwave-assisted decomposition of metal complexes of pentadentate BTSC. Thus, pure Cu_{7.2}S₄, Pd₁₆S₇, and ZnS metal sulfides NPs were synthesized.

1.1 Pentadentate Bis-thiosemicarbazones (BTSC)

Thiosemicarbazone (TSC) is a class of N[^]S ligands with primitive potential as biological agents (antiviral, antibiotic and antifungal).¹ The earliest report of TSC dates back to 1960s when TSC was employed as a probe for ketones.² Since their discovery, TSC compounds have been extended as probes for metal ions, as catalysts, and in precursor chemistry to synthesize metal sulfide NPs.^{3–6} In recent decades, attention has been extended to bis-thiosemicarbazone (BTSC), focusing more on tetradentate BTSC. In fact, few tetradentate BTSC complexes, e.g., [Cu(ATSM)], have successfully reached clinical trials as anticancer agents and diagnostic probes for imaging cardiac hypoxia.⁷ Pentadentate BTSC, such as 2,6-diacetylbenzene-bis(*N*-(4)-ethyl-thiosemicarbazone), have also been studied for their antitumor effects.⁸

In general, mono and bis-TSC are attractive because of the ease of derivatization of the ligand.⁹ Therefore, TSC can bear different -R substituents (**Scheme 1**).¹⁰ The derivatization of TSC can occur via the carbonyl or thiosemicarbazide moiety. Thus, there is a constant increase in the TSC library. The derivatization of TSC has also been extended to BTSC, where symmetrical and asymmetrical BTSC have been explored for their biological activities.¹¹ One of the benefits of derivatizing TSC is that the basic N[^]S donor atoms can be increased. Thus, while the basic TSC binds in bidentate coordination using the thiol/thione and imine pocket, a higher degree of TSC denticity has been reported.^{12,13} The derivatization of TSC is also crucial because NP conjugate of TSC can be accessed in this manner.^{14,15}

Scheme 1. Selected coordination modes of mono-TSC (A, B), tetradentate BTSC (C, D) and pentadentate BTSC modes (E).

Pentadentate BTSC can bind to metal ions in neutral and anionic forms through the lone pair from diimine N[^]S-core and the dicarbonyl donor atom (**Scheme 2**), i.e. pyridinic nitrogen and anionic

disulfur, giving rise to a highly conjugated system with pi-network consisting of alternating single and double bonds and bond length averaging between single and double bond. The coordination trend of the BTSC metal complex is vast because the metal centre influences the charge and coordination.¹⁶

Scheme 2. Complexation of pentadentate BTSC with M^{2+} .

TSC is also attractive because of their affinity for soft and hard metals.¹⁷ Thus, TSCs have been used to recover metal ions from an aqueous solution, simultaneously as a sensor for metal poison in food and beverages.^{18,19} In recovering metal ions from an aqueous solution, TSC is often anchored covalently on an NP (support) to ease the conjugate's recovery, thus limiting TSC leaching.²⁰ Consequently, graphene and cellulose have been conjugated with mono-TSC to recover metal ions from an aqueous solution.^{21,22} The graphene/cellulose-TSC conjugate showed an affinity for soft metal, as indicated by its high adsorption capacity.^{21,23}

The varieties of coordination modes adopted by mono-TSC complexes make mono-TSC complexes an invaluable homogenous catalyst for oxidation and reduction, hydrogenation, alcoholysis and condensation reaction.^{5,6} Mono-TSC can adopt the pincer-type coordination effective in carbon-carbon coupling of aryls.²⁴ The inherent N⁺S donor atoms are also beneficial for many catalyst activities due to their air stability compared to traditional phosphine-based ligands.²⁵ Recently, studies have shifted towards heterogeneous catalysts due to the challenges associated with recovering spent homogeneous catalysts.²⁶ Therefore, mono-TSC complexes are conjugated with NPs. Many studies have utilized mono-TSC terminal amine as the binding site for the NP.²⁰ Polystyrene was covalently conjugated to TSC as a heterogeneous catalyst for the oxidation of alkenes and alcohol.²⁷ The carbonyl moiety of mono-TSC has also been explored as the anchoring site of NP.²⁸ Fe₃O₄ was conjugated with the mono-TSC copper complex via the carbonyl moiety and was employed as an Ullmann-type catalyst in the arylation of imidazole with iodo-benzene.

Mono-TSC is an invaluable source of sulfur atoms. Therefore, there is also a growing trend in using mono-TSC in precursor chemistry, especially as a single-source precursor in synthesizing metal sulfide NPs.^{29,30} The inherent N³S TSC donor atoms have a varying affinity for metal ions; S have an affinity for soft metals, and N has an affinity for hard metals.³¹ Therefore, the metal complexes of mono-TSC are not limited to the transition metals. Lanthanides, actinides and alkali metal complexes have all been reported.^{32–34} Therefore, previously difficult-to-synthesize metal sulfides and bimetallic are now easily accessible in higher purity.^{35–37}

Mono-TSCs are synthesized by condensing thiosemicarbazide with a carbonyl (aldehyde or ketones).¹⁰ BTSC is synthesized similarly, except that thiosemicarbazides are condensed to two arms of dicarbonyl, thus opening the path for pentadentate BTSCs when the dicarbonyl backbone contains a donor atom, resulting in an S²N²R₄N²S binding pockets.³⁸ In lieu, different binding pockets S²N²N²N²S, S²N²S²N²S and S²N²O²N²S have been reported for pentadentate BTSC (**Scheme 3**).^{39,40} This thesis focuses on the S²N²N²N²S binding pocket obtained from the 2,6-diacetyl-pyridine derivatives.

Scheme 3. General structure of BTSC showing the dicarbonyl backbone, N²S core, and diamine tails.

1.2 Thiosemicarbazones Nanoparticle Conjugate

TSC are attractive molecules, especially in their biological activities. However, for practical applications, TSC ligands are conjugated with support to ease the recovery of spent TSC or to target specific sites.^{14,15} The structural flexibility of TSC is crucial in achieving the conjugation of TSC with support. The covalent anchoring of TSCs onto NPs is feasible via two approaches.

The first approach involved the reaction between thiosemicarbazide and carbonyl/ketone-bearing NPs. This is practical for carbon-based NPs. Ribose, galactose, glucose, and graphene-TSC NPs conjugates have been synthesized using this approach.^{41–43} The reaction between the carboxylic acid

moiety of graphene oxide and TSC's terminal amine forms an amide bond. Similarly, the reaction between acryl-chloride moiety of carbon nanotubes and TSC's terminal amine has also been used to form an amide bond to anchor TSCs covalently.²⁰

The second approach involves the covalent reaction of TSC with pre-functionalized NPs. This is the most common approach used to synthesize TSC-NP conjugates. The simplest form is to utilize TSC's terminal-NH to form a covalent bond between TSC and halogen pre-functionalized NPs. Alternatively, TSC may be derivatized with different functional groups to explore the affinity by relying on the chemistry of individual NP.⁹

1.3 Thiosemicarbazones in Suzuki-Miyaura Cross-Coupling Reaction

Thiosemicarbazone (TSC) and its metal complexes are widely known for their biological activities. However, their catalytic activities have also been gaining attention. Transition metal complexes of TSC are essential catalysts in various chemical reactions, including cross-coupling of aryls.^{5,6} The enhanced catalytic activities of TSC metal complexes have been associated with the air stable N³S donor atoms. The donor atoms are responsible for the interesting stereochemical, electrochemical, and electronic properties important for catalytic activities.^{44,45} The donor atoms are also responsible for the varieties of coordination modes adopted by TSC, including the pincer motif, which is vital for many catalytic reactions.^{24,46} The chelate pocket of TSC, especially in multidentate coordinated TSC, is also essential for the stability of catalysts.⁴⁷

Generally, the metal centre of a catalyst functions by acting as the binding site for the catalytic reaction, and the surrounding ligands and co-ligands offer the appropriate geometrical and electronic configuration toward the desired transition state for the required chemical reaction.⁴⁸ A homogenous catalytic system is attractive because the catalytic process can occur under a mild condition, offering high chemo- and regio-selectivity and catalytic activities.⁴⁶ However, since the catalyst phase is the same as the reactant and products, more energy and material are required to separate the desired products. This is a significant drawback for homogenous catalysts.⁴⁸ Thus, the quest to recover, regenerate, and reuse catalysts has led to a significant shift in the design of many catalysts. Recent catalyst designs have seen the use of insoluble NPs or the immobilization of traditional homogenous catalysts onto support such as NP.²⁸ However, the new interaction, e.g., the covalent bond between the support and metal complex, may negatively impact the electronic state of the metal centre, thus altering the catalytic activities.⁴⁸

Pd-based complexes used in the Suzuki-Miyaura cross-coupling type reaction have received the most attention because of their industrial importance.⁴⁹ The reaction involves the coupling of organoboranes and organic electrophiles in the presence of a base.^{50,51} Thus, reports that enhance the field continue to grow.⁵⁰ The mechanism that governs Pd-based cross-coupling has been extensively studied.⁵² The catalytic cycle commences with the active Pd moiety, i.e., $[Pd^0L_2]$, which is succeeded by the oxidative addition of the aryl halide ($Ar-X$) to afford *trans*- $ArPdXL_2$ complex, this is followed by the nucleophilic attack on the *trans*- $ArPdXL_2$ complex, resulting in transmetallation, the product is finally obtained by reductive elimination (**Scheme 4**).⁵²

Scheme 4. Mechanism of Suzuki-Miyaura cross-coupling reaction

1.4. Homogenous Thiosemicarbazone Catalyst

In general, homogenous catalysts have received much attention due to their higher catalytic and selectivity rates. A phosphorus-based ligand characterized the traditional Pd catalysts used in the Suzuki-Miyaura reaction; the phosphorus ligand provides steric hindrance, essential during transmetallation and reductive elimination.^{53,54} TSC Pd complex has been synthesized to include phosphorous ligands, enriching its composition alongside the intrinsic N[^]S donor atoms. This design enhanced the catalytic performance of TSC catalyst (**Scheme 5**).⁵⁵ The performance of phosphine-based TSC catalysts has also been enhanced by introducing additional ligands, highlighted by the effect of electron withdrawing and electron donating groups on the coupling of haloaryl with organoborane.⁵⁵ Among the tested ligands ($-OCH_3$, CH_3 , H , Cl and NO_2), the electron-donating ligand was the most efficient catalyst for the Suzuki-Miyaura-type reaction.

Scheme 5. Phosphine-based TSC Pd complex for Suzuki-Miyaura cross coupling reaction. Adopted from Ref.⁵⁵

Investigating the impact of a more extensive ligand system is a practical tool in designing TSC catalysts for cross-coupling reactions. Thus, bis-diphenyl-phosphine ferrocene, bis-phenyl-phosphine and phenyl-phosphine TSC Pd complexes were compared in Suzuki-Miyaura-type reaction (**Scheme 6**). The catalytic performance of the bis-diphenyl-phosphine ferrocene-containing TSC Pd complex was superior to other catalysts, even in mild catalytic conditions. The high catalytic activities were attributed to the extensive ligand system.⁵⁶

Scheme 6. Phosphine-based TSC Pd complex with extensive ligand system for Suzuki-Miyaura cross coupling reaction. Adopted from Ref.⁵⁶

Nitroso-2-naphthol and quinoline-8-ol were also investigated as ancillary ligands as an alternative to the traditional phosphine-based ligand (**Scheme 7**).⁵⁷ The catalyst was adequate for coupling of wide range of haloaryl compounds with boronic acid, including the activation of C-F, C-I and C-Cl.⁵⁷ The reaction also proceeded at room temperature, however at longer reaction time.⁵⁷

Scheme 7. TSC Pd complex with ancillary ligands for Suzuki-Miyaura cross-coupling reaction. Adopted from Ref.⁵⁷

The pincer complexes are known for their excellent catalytic activities. This type of ligand is characterized as moisture, air and thermal-stable.²⁴ Tridentate TSC ligands usually conform to the pincer motif.⁵⁸ Salicylaldehyde TSC Pd complex was employed as an air and moisture-stable catalyst for coupling organoborane with aryl halides (**Scheme 8**).⁵⁹ The optimum catalytic condition was obtained in DMF solution at 100°C.⁵⁹ The coupling can also occur under a mild catalytic condition. However, activation of chloride substituent was low as compared to bromide substituent.⁶⁰

Scheme 8. Pincer conform TSC Pd complex for Suzuki-Miyaura cross coupling reaction. Adopted from Refs.^{59,60}

1.5 Heterogenous Thiosemicarbazone catalyst

In the quest for a sustainable chemical process, relevance is given to the design of heterogeneous TSC catalysts. In lieu, Pd complexes TSC were conjugated with SiO₂ NPs. The covalent conjugation of TSC Pd complex and SiO₂ NP was achieved by reacting –NH pre-functionalized SiO₂ with carbonyl pre-functionalized TSC. The TSC–NP conjugate shows high catalytic activities and selectivity, and the spent catalyst can be recovered and regenerated for reuse (**Scheme 9**).⁶¹ Carbohydrate was employed as the carbonyl constituent in the synthesis of TSC for the Suzuki-Miyaura type reaction. The

coupling reaction was achieved in high yield at 60 minutes reaction time. Substituted aryl chloride at the ortho position achieved the lowest coupling.⁶²

Scheme 9. TSC-Pd heterogeneous catalyst for Suzuki-Miyaura cross coupling reaction. Adopted from Ref.⁶¹

1.6 Thiosemicarbazone Complexes as a Single-Source Precursor

TSCs are an important source of sulfur due to the inherent N[∧]S donor atoms. Therefore, TSC metal complexes are ideal for the synthesis of metal sulfide.⁶³ Thus, several metal sulfide NPs have been reported, including transition metals and lanthanides.^{37,63,64} Usually, the metal sulfide is obtained via the thermal decomposition of the TSC metal complex. The decomposition commences with eliminating alkene and rearrangement to form the metal sulfide NP (**Scheme 10**).³⁷

Scheme 10. Thermal decomposition of TSC complex for the synthesis of metal sulfide. Adopted from Ref.³⁷

1.7 Thiosemicarbazone Nanoparticle Conjugate in Metal Binding

TSC are ideal for metal binding due to chelating properties. The inherent N[∧]S donor atoms have different affinity for hard and soft acids.⁶⁵ TSC are anchored on a support (NP) during the binding and recovery of metal ions. In lieu, multiwall carbon nanotubes (MWCNs), carboxylate functionalized MWCNs and carboxylate functionalized MWCNs anchored with 1-isatin-3-TSCs was investigated for the adsorption of Pb²⁺ ions.²⁰ Increasing the solution pH value from 1 to 5.5 was favourable to all the adsorbents. Above the optimum pH (5.5), the surfaces of the carboxylate functionalized MWCNs and carboxylate functionalized MWCNs anchored with 1-isatin-3-TSC were characterized by the dissolution of the carboxylic group and protonation of amino groups, respectively. The adsorption

capacity of carboxylate functionalized MWCNs anchored with 1-isatin-3-TSC was superior (63.67 mg/g), when compared with the carboxylate functionalized MWCNs (7.36 mg/g). This showed that while the contribution of the carboxylate functional group ($-\text{COOH}$, a hard base) was lost, the thiol (SH) on the TSC retained its binding capacity, thereby contributing to its adsorption capacity.

Another study has also highlighted the impact of the N^S donor atoms by conjugating graphene oxide with TSC. Graphene oxide conjugated with TSC improved the affinity of the conjugate for Hg^{2+} ions.⁴³ The improved affinity for Hg^{2+} was caused by the reaction of the donor atoms (S and N) with Hg^{2+} ions, which results in a strong surface complexation reaction. Mesoporous silica conjugated with 5-*tert*-butyl-2-hydroxybenzaldehyde TSC. The resulting adsorbent was used for the removal of Pd^{2+} .⁶⁶ At the optimum pH (3.5), in the presence of 10 mg/L competing ions (Ca^{2+} , Fe^{3+} , Co^{2+} , Mg^{2+} , Zn^{2+} , Cu^{2+} , K^{+} , Na^{+} , Ag^{+} , Ru^{3+} , Al^{3+} , Ba^{2+} and Pt^{2+}), the SiO_2 -TSC conjugate was selective for Pd^{2+} at 2 mg/L initial concentration, with slight loss of activities after the 9th cycle of the regeneration of the SiO_2 -TSC conjugate.⁶⁷

NP conjugate of TSC has also been used for preconcentration and detection of metal ions. Alumina-TSC conjugate was employed for the preconcentration and selective extraction of Cr oxyanions in the presence of competing metal ions.⁶⁸ The affinity of the Alumina-TSC towards Cr^{3+} oxyanion increased with increasing solution initial pH from 4 to 7, with adsorption capacity between the range 10 to 760 $\mu\text{mol/g}$. In contrast, the affinity for $\text{C}_2\text{O}_7^{2-}$ increased as the initial pH solution decreased from 4 to 1, with adsorption capacity between 100 to 400 $\mu\text{mol/g}$. Thus, it is viable to selectively extract chromium oxyanions by manipulating the initial solution pH. Polystyrene-1-phenyl-1,2-propanedione-2-oxime-TSC conjugate was employed to preconcentrate Cu^{2+} ions in aqueous solution, soil and food samples.⁶⁹ The polystyrene-TSC conjugate selectively complexed Cu^{2+} at initial solution pH 5. The adsorbed Cu^{2+} exhibits high stability in strong acid and alkaline mediums. However, competing ions such as Fe^{3+} and Hg^{2+} remain a challenge.⁶⁹

Mesoporous SiO_2 -TSC conjugate was employed to detect and remove Cu^{2+} from an aqueous solution.⁶⁷ The removal of Cu^{2+} ions was influenced by the solution pH, with the maximum adsorption capacity of 176.27 mg/g. The removal of optimum Cu^{2+} ions was observed at a neutral solution pH. Therefore, while TSC-based adsorbents show high adsorption capacity and can function in selective extraction and preconcentration, competing ions remain challenging. However, this shortcoming associated with competing ions can be overcome by manipulating the solution's initial pH since N^S donor atoms present in TSCs can function independently at opposing pH values.

1.8 Aim of this Work

The aim of this thesis is to synthesize a range of pentadentate BTSC and their NP conjugate (BTSC–NP). The BTSC–NP conjugate is used for the binding Pd^{2+} . The Pd^{2+} coordinated BTSC–NP is further employed as a catalyst in the Suzuki-Miyaura-type cross-coupling reactions. The conjugation of NP with BTSC was attempted via the dicarbonyl backbone and the diamine tail (**Scheme 11**). A further aim was to use BTSC metal complexes as a facile single-source precursor in the synthesis of metal sulfides.

The aim of the project was achieved by following these objectives:

- Synthesis of pentadentate BTSC and their complexes and derivatization of pentadentate BTSC to bear additional functional groups at the dicarbonyl backbone and the diamine tails.
- The synthesis of pentadentate BTSC functionalization with dopamine hydrochloride, (3-aminopropyl)-triethoxysilane or (3-chloropropyl)-trimethoxysilane. Covalent anchoring of pentadentate BTSC with Fe_3O_4 , SiO_2 and Fe_2O_3 .
- Adsorption of Pd^{2+} ions in aqueous solution with $\text{Fe}_3\text{O}_4@/\text{SiO}_2$ -APTES-BTSC conjugates and investigation of the adsorption isotherm and the effect of hydrochemistry
- Carbon-carbon coupling of aryl compounds in the Suzuki-Miyaura-type reaction using SiO_2 -APTES-BTSC- Pd^{2+} as heterogenous catalyst
- Synthesis of metal sulfides using BTSC metal complexes of Cu, Pd and Zn.

Scheme 11. NP conjugate of pentadentate BTSC anchored through dicarbonyl backbone or diamine tail.

Chapter 2. Results and Discussion

2.1 Synthesis of Pentadentate BTSC and their NP Conjugates

Pentadentate Bis-Thiosemicarbazones (BTSC) are an essential class of N⁴S donor ligands for synthesizing metal complexes with various applications.⁸ BTSC ligands comprise a dicarbonyl backbone and a core N⁴S core.⁷⁰ Both the dicarbonyl backbone and N⁴S core can be derivatized to bear different constituents and functional groups, thus expanding the BTSC library.

The primary consideration of this study was to synthesize BTSC with different anchoring groups at the dicarbonyl backbone or at the amine tail, which can further react with dopamine hydrochloride, (3-aminopropyl)-triethoxysilane or (3-chloropropyl)-trimethoxysilane, to finally afford a BTSC that can covalently bond with NPs in the simplest chemical reaction. The four functional groups of interest are carboxylate, hydroxyl and halogen. This aim was achieved by first synthesizing a series of thiosemicarbazides, i.e., the N⁴S core, followed by the synthesis of the dicarbonyl (backbone) and finally, the condensing of the dicarbonyl with thiosemicarbazides to afford a series of pentadentate BTSC.

2.2 Results and Discussion

2.2.1 Synthesis of Thiosemicarbazides

Two methods have previously been described for the synthesis of thiosemicarbazides.⁷¹ 1) a two-step reaction involving the treatment of carbohydrazide with isothiocyanates or ammonium thiocyanate, 2) a one-pot reaction involving the treatment of boiling dithiocarbamate salt with hydrazine.⁷¹ The one-pot is ideal for water-soluble primary amine, gives a reasonable yield, and does not involve the highly toxic thiophosgene. After cooling, thiosemicarbazide is obtained as a colourless precipitate in an aqueous solution (**Scheme 12**). Possible contamination arises from the reaction of thiosemicarbazide terminal amine with common solvents such as acetone and ethyl acetate. The synthesized series of thiosemicarbazides are presented in **Scheme 13**. The hydrazine protons of the thiosemicarbazide appeared at the opposing end of the proton NMR spectrum (**Table 1**).

Scheme 12. General method for the synthesis of thiosemicarbazide

2.2.2 Synthesis of 2,6-diacetyl-pyridine (DAP) derivatives

With the successful synthesis of the thiosemicarbazide. The study proceeds to the synthesis of the dicarbonyl backbone and its derivatives. The dicarbonyl was synthesized by acetylation of substituted pyridine (**Scheme 14**).^{72,73} First, substituted pyridine and pyruvic acids were dissolved in an aqueous acidic solution. The addition of ammonium thiosulfate salt in the presence of AgNO₃ caused the evolution of CO₂. Substituted 2,6-diacetyl-pyridine was purified via column chromatography using neat DCM. 4-chloro-pyridine and 4-bromo-pyridine were purchased as hydrochloride salts. The

hydrochloride salts were basified with saturated NaOH before acetylation to avoid generating silver chloride salts. In the case of 4-(diethyl-phosphite)-2,6-diacetyl-pyridine, substituted pyridine, i.e., 4-(diethyl-phosphite)-pyridine, was obtained via coupling of diethyl-phosphite with 4-bromo-pyridine in the presence of triethylamine using Pd-catalyst to eliminate triethylamine-hydrobromide. The product 4-(diethyl-phosphite)-pyridine was subsequently treated with pyruvic acid to obtain the 4-(diethyl-phosphite)-2,6-diacetyl-pyridine.

Scheme 14. General method for the synthesis of substituted 2,6-diacetyl-pyridine derivatives.

A series of DAP backbones were synthesized (**Scheme 15**), primarily focusing on synthesizing dicarbonyl with additional functional groups to allow functionalization with linkers and the subsequent covalent functionalization with NP. Another benefit of functionalizing the dicarbonyl backbone is to improve the solubility of the resulting BTSCs. The dicarbonyl is characterized by a relatively low isolated yield (< 12%). The lowest isolated yield of 2% was obtained 4-(diethyl-phosphite)-DAP.

Scheme 15. Series of 2,6-diacetyl-pyridine derivatives synthesized in this study.

2.2.2.1 ^1H NMR of Dicarbonyl

The representative ^1H NMR spectra of the dicarbonyl are presented in **Fig. 2** and **3** for 4-methyl-isonicotinate-2,6-DAP and 4-(diethyl-phosphite)-DAP. The most identifying peaks are the two symmetrical $-\text{CH}_3$ peaks associated with the diacetyl, which appeared at $\delta = 2.8$ and 2.7 ppm. The additional $-\text{CH}_3$ of the ester moiety for compound **11** appeared at 4.03 ppm. The symmetric $-\text{CH}_2$ and $-\text{CH}_3$ parts of the phosphonic acids appeared at 4.28 and 1.38 ppm.

Fig. 2. ^1H NMR spectrum of 4-methyl-isonicotinate-2,6-DAP measured in CDCl_3

Fig. 3. ^1H NMR spectrum of 4-(diethyl-phosphite)-DAP measured in CDCl_3

2.2.3 Synthesis of pentadentate Bis-Thiosemicarbazones

Having successfully obtained the substituted dicarbonyl, series of BTSC was obtained via a condensation reaction involving 2,6-diacetyl-pyridine or substituted 2,6-diacetyl-pyridine (ratio 1) with thiosemicarbazide (ratio 2) in acetic acid solution (**Scheme 16**). The reaction was catalyzed with 0.1 mL of CF_3COOH . BTSCs were obtained as yellow solids with reasonable yields (52 – 66%). Earlier attempts to synthesize BTSC in ethanol and methanol using acetic acid as a catalyst yielded impure products.^{74,75} This is due to the solubility of the thiosemicarbazide precursors.

Scheme 16. General method for the synthesis of BTSC.

Using the method mentioned earlier, commercially available 2,6-diacetyl-pyridine was used to synthesise a series of BTSC presented in **Scheme 17**.

Scheme 17 A series of BTSC starting with 2,6-diacetyl-pyridine

2.2.3.1. ¹H NMR of Bis-Thiosemicarbazones

The structural information of all the new compounds was elucidated using ¹H NMR. Representative spectra are presented in Fig. 4 and 5. The most identifying peaks are the two symmetrical -CH₃ at both arms of the dicarbonyl backbone, which appeared upfield at around 2.59 ppm, and the two characteristic hydrazine protons appearing downfield at around 15.08 and 11.18 ppm for 2,6-diacetylpyridine-bis-4-*N*-2-pyridyl BTSC (**Table 2**). One of these hydrazine protons appeared upfield in thiosemicarbazide; however, when BTSC was formed, the signal appeared downfield. The three aforementioned characteristic peaks have been reported at 2.45, 10.35 and 8.45 ppm, respectively.⁷⁶ A triplet dividing both arms of the BTSC appeared at 8.01 ppm. This triplet is absent with 4-substituted BTSC.

2.2.3.2 Molecular Structure of Bis-Thiosemicarbazones

The crystal and molecular structures of 2,6-diacetylpyridine-bis-4-*N*-2-pyridyl-BTSC and its -bromo derivatives are presented in **Fig. 7 – 9** as the representative structure, and the crystallography data are presented in **Table 3**. Both compounds were recrystallized from hot DMSO. 2,6-diacetylpyridine-bis-4-*N*-2-pyridyl-BTSC was crystallized as a dimeric compound in the triclinic space group *P*-1, 4-bromo-2,6-diacetylpyridine-bis-4-*N*-2-pyridyl-BTSC was crystallized in the monoclinic space group *P* 2₁/*n*. The ligand arms showed open conformations; the conformations were obtained through an *E* configuration about the two hydrazone motifs.^{77,78} The crystal arrangement of 2,6-diacetylpyridine-bis-4-*N*-2-pyridyl-BTSC is similar to a tilted edge-to-face herringbone arrangement with three co-crystallized DMSO. 4-bromo-2,6-diacetylpyridine-bis-4-*N*-2-pyridyl-BTSC unit cell also showed a flattened herringbone packing with translated related moieties co-crystallized with DMSO. The average bond distances between C=S (1.69) and C=N (1.29) are consistent with the literature.⁷⁷

Fig. 7. Molecular structure of 2,6-diacetylpyridine-bis-4-*N*-2-pyridyl-BTSC showing two independent BTSC molecules with 3 co-crystallized DMSO in BTSC3DMSO, ellipsoids drawn at the 50% probability level.

2.2.4 Anchoring Bis-Thiosemicarbazone with APTES

Having successfully synthesized BTSC, we proceed with the covalent anchoring of BTSC with different linkers. This is important because one of the goals of this thesis is the covalent anchoring of BTSC with NP. The linker can bind with BTSC and NP at opposite ends. Therefore, three linkers (3-aminopropyl)-triethoxysilane (**APTES**), 3-chloropropyl-trimethoxysilane (**CPTES**), and dopamine hydrochloride were chosen in this study. APTES was anchored with 2,6-diacetyl-pyridine-bis-(4-*N*-2-ethylaniline)-BTSC via the dicarbonyl backbone (**Scheme 18**), while CPTES and dopamine hydrochloride were anchored with 2,6-diacetylpyridine-bis-(4-*N*-3-hydroxyl-2pyridyl)-BTSC and 2,6-diacetylpyridine-bis-(4-*N*-chlorophenyl)-BTSC via the diamine tail (**Scheme 19**). The covalent conjugation of 2,6-diacetyl-pyridine-bis-(4-*N*-2-ethylaniline)-BTSC with (3-aminopropyl)-triethoxysilane was achieved in THF, while the covalent conjugation of 2,6-diacetylpyridine-bis-(4-*N*-3-hydroxyl-2pyridyl)-BTSC with 3-chloropropyl-trimethoxysilane and 2,6-diacetylpyridine-bis-(4-*N*-chlorophenyl)-BTSC with dopamine hydrochloride was achieved in DMF. APTES and CPTES are prone to hydrolysis in DMF. Thus, one arm of APTES and CPTES were isolated as hydrolyzed parts.

Scheme 18. Conjugation of 2,6-diacetyl-pyridine-bis-(4-*N*-2-ethylaniline)-BTSC with APTES

2.2.4.1 ¹H NMR of Bis-Thiosemicarbazones conjugate of APTES

The most identified peaks are the pairs of two symmetrical -CH₃, which appeared at 1.31 and 2.52 ppm as part of the parent BTSC. Additional protons in the upfield correspond to the APTES moiety, which includes the three -CH₃ at 1.58 ppm and the six -CH₂ appearing at 1.23, 2.73 and 3.83 ppm. The new amide bond was found at 5.66 ppm (**Fig. 10**). The symmetric hydrazine protons appeared downfield at 8.92 and 9.19 ppm, consistent with the parent BTSC described earlier (**Fig. 11**).

Fig. 10. ^1H NMR spectrum of 4-chloro-2,6-diacetyl-pyridine-bis-(4-N-2-ethylaniline)-BTSC-APTES conjugate, sample measured in CDCl_3 .

Fig. 11. ^1H NMR spectrum of 4-chloro-2,6-diacetyl-pyridine-bis-(4-N-2-ethylaniline)-BTSC-APTES conjugate showing a magnified portion of the spectrum. Sample measured in CDCl_3 .

2.2.5 Anchoring Bis-Thiosemicarbazone with Dopamine

Having conjugated BTSC with (3-aminopropyl)-triethoxysilane at the dicarbonyl site, we focus on conjugating BTSC with dopamine at the diamine tail. 2,6-diacetylpyridine-bis-(4-N-chlorophenyl)-TSC was dissolved in DMF, and Et_3N was added. Dopamine hydrochloride was added (**Scheme 19**).

Scheme 19. Conjugation of Compound **24** with dopamine

2.2.5.1 ¹H NMR of Bis-Thiosemicarbazone with Dopamine

The ¹H NMR spectra showed the symmetrical -CH₃ at 2.55 ppm, and the alkyl chain from the dopamine moiety appeared at 2.38 and 2.69 ppm (**Fig. 12**). The new amide bond appeared at 6.56 ppm. The aryl moiety of the dopamine appeared at 6.69, 7.35 and 8.81 ppm. The dicarbonyl signals appeared at 7.86 and 8.56 ppm. The hydrazine protons appeared downfield at 10.24 and 10.81 ppm (**Fig. 13**). Thiol-thione tautomeric character is visible in the ¹H NMR spectrum of 2,6-diacetylpyridine-bis-(4-*N*-chlorophenyl)-BTSC–Dopamine conjugate. This character is also visible in the ¹H NMR spectrum of unconjugated 2,6-diacetylpyridine-bis-(4-*N*-chlorophenyl)-BTSC (**Fig. 14**).

Fig. 14. Magnified ^1H NMR spectrum of unconjugated 2,6-diacetylpyridine-bis-(4-N-chlorophenyl)-BTSC. Showing the minor tautomeric characters. Sample measured in DMSO-d_6 .

2.2.6 Synthesis of Pentadentate Bis-Thiosemicarbazone Metal Complexes

The BTSC metal complexes were obtained by deprotonating BTSC with triethylamine, followed by coordination with metal ions. The metal complexes were obtained in good yield (55 – 90%).

2.2.6.1. ^1H NMR of BTSC complexes.

The Pd complexes spectra showed the most interesting features due to the bonding. Several single protons were observed rather than the appearance of several two protons signals. The coordination of BTSC with Pd ions caused the BTSC Pd complex to lose its symmetry. A representative ^1H NMR is presented in **Fig. 15**. The usual single protons of the free ligand associated with the two $-\text{CH}_3$ from the dicarbonyl backbone now appeared as two singlets upfield $\delta = 2.3$ and 2.6 ppm, and the dicarbonyl aryl protons also appeared as two asymmetrical protons at $\delta = 7.9$ and 7.88 ppm. The aryl protons at the ortho and meta position of the thiosemicarbazide moiety are also asymmetric, appearing at $\delta = 8.87$ and 8.32 ppm and $\delta = 7.04$ and 8.11 ppm, respectively. The uncoordinated hydrazine proton appeared as a singlet downfield ($\delta = 10.3$ ppm) in contrast to the two hydrazine signals observed for the free ligand.

Fig. 15. Magnified portion of the ^1H NMR spectrum of Pd complex of 2,6-diacetylpyridine-bis-(4-*N*-2-pyridyl)-BTSC measured in $\text{DMSO}-d_6$.

The representative ^1H NMR of Zn complexes is presented in **Fig. 16**. The Zn complex has retained its symmetry. Thus, most signals appeared as two protons in the NMR spectra. The two symmetrical CH_3 protons appeared as a single at $\delta = 2.3$ ppm, and the uncoordinated hydrazine protons appeared at $\delta = 9.0$ ppm. The distinguishable proton which divides both arms appeared as a triplet at $\delta = 8.1$ ppm, and the aryl protons from the thiosemicarbazide moiety appeared at $\delta = 7.05, 7.76, 7.87$ and 8.28 ppm. Unlike Pd complex of BTSC, the Zn complex of the pentadentate BTSC has retained its symmetry.

Fig. 16. Magnified portion of the ^1H NMR spectrum of Zn complex of 2,6-diacetylpyridine-bis-(4-*N*-2-pyridyl)-BTSC measured in $\text{DMSO}-d_6$.

2.2.6.2 Molecular Structure of Bis-Thiosemicarbazone Metal Complexes

Single crystals, suitable for X-ray diffraction, were obtained for Pd and Zn complexes of 2,6-diacetylpyridine-bis-(4-*N*-2-ethylaniline)-BTSC; Cu complex of 2,6-diacetylpyridine-bis-(4-*N*-2-ethylaniline)-BTSC was also included as part of the synthesis of metal sulfide in future studies. Cu and Pd single crystals were obtained by slow evaporation in DCM, while Zn single crystal was obtained by the vapour diffusion of pentane over DCM. The crystal structure and molecular structures are shown in **Fig. 17**, and interatomic distances and angles are given in **Table 4** and **5**. $[\text{Cu}(\text{BTSC})]$ was isolated as a dimeric neutral compound exhibiting a trigonal bipyramidal geometry. Each Cu atom is coordinated as $\text{S}^{\wedge}\text{N}^{\wedge}\text{N}^{\wedge}\text{N}^{\wedge}\text{S}$, bridging through N-imine from either arm of the BTSC. $[\text{Cu}(\text{BTSC})]$ is predominantly a thiolate complex, with an average C-S bond distance of 1.73 [Å]. The distance (3.4 [Å]) between Cu-Cu suggests no metal-metal interaction. $[\text{Pd}(\text{BTSC})]$ is a neutral mononuclear complex exhibiting square-planar coordination with a slight distortion attached in a tetradentate binding through $\text{S}^{\wedge}\text{N}^{\wedge}\text{N}^{\wedge}\text{N}$ (**Fig. 18**). The thione-thiol character of the complex is noticeable from the bond length between coordinated C-S (1.760 Å) and uncoordinated C=S (1.688 Å).

The bond distance between N–N (1.366 and 1.372 Å) and C–N (1.290, 1.311 and 1.307 Å) is intermediate between formal single and double bonds, indicative of delocalised electrons.^{70,79} [Zn(BTSC)] was also isolated as a binuclear neutral compound, exhibiting a distorted square planar coordination. Each Zn atom is surrounded by two imines (N) and two thiols (S) atoms from both arms of the BTSC, forming two pairs of five-membered rings (**Fig. 19**). Interestingly, the tetradentate coordination S^2N^2 does not include the pyridinic nitrogen. The average bond distance between M–N and M–S is comparable with reported complexes of BTSC.^{80–82}

2.2.6.3 FT-IR Spectroscopy of Bis-Thiosemicarbazone Metal Complexes

2,6-diacetyl-pyridine-bis-(4-*N*-2-ethylaniline)-BTSC and its Cu²⁺, Pd²⁺ and Zn²⁺ complexes will be selected as the representative vibration to give a specific overview of the vibration of BTSC complexes. Thus, the vibrational bands of the Cu²⁺, Pd²⁺ and Zn²⁺ complexes of 2,6-diacetyl-pyridine-bis-(4-*N*-2-ethylaniline)-BTSC are compared with the uncoordinated ligand (**Fig. 20**). The free ligands is characterized by a distinct vibrations for N–H (1591, 2959 and 3295 cm⁻¹), C=S (755, 1156 and 1258 cm⁻¹) and C=N (1259 cm⁻¹), comparable with reported TSC.^{83–86} The vibrational contribution from C–H, phenyl ring and C=C are noticeable around 530, 634, and 1318 cm⁻¹. For the BTSC metal coordinated system, a new vibration around 1720 cm⁻¹ appeared, corresponding to C=N. The initial C=N vibration (1510 cm⁻¹) shifted or/and deformed (1408 cm⁻¹ for Cu complex, 1453 cm⁻¹ for Pd complex and 1445 cm⁻¹ for Zn complex.^{87,88} The coordinative contribution from C=S and N–H is noticeable by the deformation and shifting of bands. The N–H singlet vibration (2959 cm⁻¹) in the free ligand deformed into a doublet for all the complexes. Similarly, the N–H doublet vibration (3295 cm⁻¹) in the free ligand deformed into a narrow singlet for the Cu complex, a broad singlet for the zinc complex and a wide-broad singlet for the Pd complex. The changes in the vibrations are evidence of the successful coordination of BTSC with the metal ions.

Fig. 20. FT-IR spectra of Cu^{2+} , Pd^{2+} and Zn^{2+} complexes of 2,6-diacetyl-pyridine-bis-(4-*N*-2-ethylaniline)-BTSC ligands recorded between 400 – 4000 nm.

2.2.7 Synthesis of Bis-Thiosemicarbazone NP Conjugates.

Fe_3O_4 , SiO_2 and Fe_2O_3 were the three NPs used in the thesis. Fe_3O_4 was chosen for its magnetic properties, and SiO_2 and Fe_2O_3 were selected for their biological relevance.

2.2.7.1 Synthesis of Fe_3O_4 -APTES-BTSC Nanoparticle Conjugates

Fe_3O_4 NP was conjugated with BTSC (2,6-diacetylpyridine-bis-(4-*N*-2-pyridyl)-BTSC) via the well-established 1-ethyl-3-(3-dimethylaminopropyl)carbodiimide (EDC)/*N,N'*-dicyclohexylcarbodiimide (NHS) coupling route.^{89,90} In the EDC/NHS coupling, an amide bond is formed from the reaction between carboxylate and amine functional groups (**Scheme 20**). In this case, ester-functionalized BTSC was synthesized by the condensation of Compound **1** (2-pyridyl-thiosemicarbazide) with Compound **11** (4-methyl-isonicotinate-2,6-diacetyl-pyridine). The hydrolysis of 4-methyl-isonicotinate 2,6-diacetylpyridine-bis-(4-*N*-2-pyridyl)-BTSC in DMF using saturated NaOH affords a carboxylic acid-functionalized BTSC (2,6-diacetylpyridine-4-carboxylic acid-bis-(4-*N*-2-pyridyl)-BTSC). Fe_3O_4 was obtained from a mixture of Fe^{2+} and Fe^{3+} salts via co-precipitation in a separate reaction. The obtained Fe_3O_4 NP was coated with triethoxy-(ethyl)silane (TOES) to obtain $\text{Fe}_3\text{O}_4@\text{SiO}_2$ and was conjugated with (3-aminopropyl)-triethoxysilane (APTES).⁹¹ $\text{Fe}_3\text{O}_4@\text{SiO}_2$ -APTES-BTSC was eventually obtained by reacting pre-functionalized $\text{Fe}_3\text{O}_4@\text{SiO}_2$ -APTES with carboxylate functionalized BTSC. The covalent conjugation of $\text{Fe}_3\text{O}_4@\text{SiO}_2$ -APTES with BTSC was achieved in DMF for 24 hours.

Scheme. 20. Hydrolysis of 4-methyl-isonicotinate 2,6-diacetylpyridine-bis-(4-*N*-2-pyridyl)-BTSC to afford the carboxylic functional group and conjugation of Fe_3O_4 with 2,6-diacetylpyridine-4-carboxylic acid-bis-(4-*N*-2-pyridyl)-BTSC .

2.2.7.2 ¹H NMR of Carboxylate Functionalized Bis-Thiosemicarbazone

The hydrazine protons for 4-methyl-isonicotinate 2,6-diacetylpyridine-bis-(4-*N*-2-pyridyl)-BTSC appeared at $\delta = 15.09$ and 11.20 ppm (**Fig. 21**). The most identifying signals are the two symmetrical -CH₃ groups, 2.6 ppm. while the methyl group associated with the ester functional group appeared at $\delta = 3.9$ ppm. The hydrazine protons for 2,6-diacetylpyridine-4-carboxylic acid-bis-(4-*N*-2-pyridyl)-TSC shifted downfield $\delta = 15.1$ and 11.24 ppm on hydrolysis of the ester group (**Fig. 22**).

Fig. 21. ¹H NMR spectrum of 4-methyl-isonicotinate 2,6-diacetylpyridine-bis-(4-*N*-2-pyridyl)-BTSC measured in DMSO-*d*₆.

Fig. 22. ^1H NMR spectrum of 2,6-diacetylpyridine-4-carboxylic acid-bis(4-N-2-pyridyl)-BTSC measured in $\text{DMSO}-d_6$

2.2.7.3 FT-IR Spectroscopy of Fe_3O_4 -APTES-BTSC Nanoparticles Conjugates

2,6-diacetylpyridine-bis(4-N-2-pyridyl)-BTSC spectra showed several sharp and narrow bands at 516, 639, 767, 832, 1149, 1200, 1339, 1347, 1428, 1524 and 1603 cm^{-1} . The intense band at 767, 1149, 1524 and 1603 cm^{-1} correspond to out-of-plane bending of N-H, C=N stretching, N-H bending, and C=C bond stretching, based on comparison with 3,5-dimethyl-1*H*-pyrrole-2-carboxylate-4-thiosemicarbazone.^{92,93} The C=S stretching was assigned to the band at 832 and 1428 cm^{-1} , and the aromatic ring associated C=N bond was observed at 1339 cm^{-1} . The weak broadband at 2882 and 3194 cm^{-1} suggests a symmetric N-H stretching since the asymmetric N-H band produces a strong band.^{92,93} These sets of bands appeared for 4-methyl-isonicotinate 2,6-diacetylpyridine-bis(4-N-2-pyridyl)-BTSC and 2,6-diacetylpyridine-4-carboxylic acid-bis(4-N-2-pyridyl)-BTSC. The ester group and the corresponding OH vibration for 2,6-diacetylpyridine-4-carboxylic acid-bis(4-N-2-pyridyl)-BTSC were observed as an intense band at 1727 cm^{-1} and 3247 cm^{-1} , respectively, with the appearance of a carboxylate signal at 1646 cm^{-1} (**Fig. 23**).

Fig. 23. FT-IR spectra of 4-methyl-isonicotinate 2,6-diacetylpyridine-bis-(4-*N*-2-pyridyl)-BTSC (**17-1**) and 2,6-diacetylpyridine-4-carboxylic acid-bis-(4-*N*-2-pyridyl)-BTSC (**17-2**) recorded between 400 – 4000 nm.

The pristine Fe_3O_4 exhibits two characteristic bands at 547 cm^{-1} and 3357 cm^{-1} , corresponding to Fe–O–Fe bond deformation and the O–H stretching (**Fig. 24**).⁹⁴ On coating Fe_3O_4 with TEOS, the band corresponding to the asymmetric stretching vibration of Si–O–Si bond and C–H bending appeared as an intense peak at 1067 cm^{-1} and a broad signal at 1638 cm^{-1} , respectively.⁹⁵ On pre-functionalization with APTES, a band for the symmetric N–H bending mode appeared at 2982 cm^{-1} confirming the presence of –NH functional group.⁵⁵ The covalent bonding of 2,6-diacetylpyridine-4-carboxylic acid-bis-(4-*N*-2-pyridyl)-BTSC with $\text{Fe}_3\text{O}_4@\text{SiO}_2\text{--APTES}$ forming $\text{Fe}_3\text{O}_4@\text{SiO}_2\text{--APTES--BTSC}$ caused the appearance of additional bands at 1477 cm^{-1} (C=C and C–C stretching), 1532 cm^{-1} (C=N stretching), 1591 cm^{-1} (C=S stretching) and 1606 cm^{-1} (N–H scissoring).^{22,96}

Fig. 24. FT-IR spectra of Fe_3O_4 , $\text{Fe}_3\text{O}_4@\text{SiO}_2$, $\text{Fe}_3\text{O}_4@\text{SiO}_2\text{-APTES}$ and $\text{Fe}_3\text{O}_4@\text{SiO}_2\text{-APTES-BTSC}$ recorded between 400 – 4000 nm.

2.2.7.4 Powder XRD Patterns of $\text{Fe}_3\text{O}_4\text{-APTES-BTSC}$

The powder X-ray diffraction (PXRD) patterns of the Fe_3O_4 , $\text{Fe}_3\text{O}_4@\text{SiO}_2\text{-APTES}$ and $\text{Fe}_3\text{O}_4@\text{SiO}_2\text{-APTES-BTSC}$ NPs are shown in **Fig. 25**. The Miller indices (202, 311, 400, 422, 511, 404, 533 and 731) observed from the PXRD patterns of the Fe_3O_4 NPs were comparable with spinel magnetite phase

(JCPDS: 19-0629). The crystallite size was calculated using the Debye–Scherrer equation $D = 0.89\lambda/\beta\cos(\theta)$, where $\lambda = 0.7093$ (wavelength), β is the Full Width at Half Maxima (FWHM) of the most substantial peak (311). The sharp peaks align with the nanocrystalline character (crystallinity index = 78% and crystallite size = 72 nm) of the Fe_3O_4 sample. Coating the Fe_3O_4 NPs with the silane derivatives (Triethoxy(ethyl)silane (TOES) and (3-aminopropyl)-triethoxysilane (APTES)) caused a reduction in the crystallinity index to 48% and an increase in the crystallite size (84 nm). Finally, covalent functionalization with 2,6-diacetylpyridine-4-carboxylic acid-bis-(4-N-2-pyridyl)-BTSC further reduced the crystallinity index to 35% and a slight increase in the crystallite size (86 nm), in keeping with the surface functionalization through non-crystalline molecular entities.

Fig. 25. PXRD patterns of Fe_3O_4 , $\text{Fe}_3\text{O}_4@\text{SiO}_2\text{-APTES}$ and $\text{Fe}_3\text{O}_4@\text{SiO}_2\text{-APTES-BTSC}$. JCPDS 19-0629 represents magnetite Fe_3O_4 .

2.2.7.5 SEM and EDX Investigation of $\text{Fe}_3\text{O}_4@\text{SiO}_2\text{-APTES-BTSC}$ Nanoparticles

Scanning electron microscopy (SEM) images of the $\text{Fe}_3\text{O}_4@\text{SiO}_2\text{-APTES-BTSC}$ showed non-defined nanoparticles with some agglomeration (**Fig. 2.14**). The Energy Dispersive X-ray (EDX) analysis showed the presence of Fe, O, Si, C, N and S (**Fig. 2.15**).

Fig. 26. SEM image of $\text{Fe}_3\text{O}_4@\text{SiO}_2\text{-APTES-BTSC}$ NPs

Fig. 27. EDX analysis of Fe₃O₄@SiO₂-APTES-BTSC

2.2.7.6 Thermogravimetry Analysis.

The thermal behaviour of the NPs (Fe₃O₄, Fe₃O₄@SiO₂-APTES and Fe₃O₄@SiO₂-APTES-BTSC) were examined using thermogravimetric analysis (TGA) under an inert (N₂) atmosphere (**Fig. 2.16**). Minimal weight loss was observed for the non-functionalized Fe₃O₄ NPs compared to Fe₃O₄@SiO₂-APTES and Fe₃O₄@SiO₂-APTES-BTSC. The Fe₃O₄ NPs was characterized by a two-step weight loss corresponding to adsorbed solvents (0.74%) and the release of surface functional groups or residual organic entities of Fe₃O₄ NPs (9.2%), respectively.⁹⁷ The amino-functionalized Fe₃O₄@SiO₂-APTES NPs are characterized by three-step weight losses (14.4%). The Fe₃O₄@SiO₂-APTES-BTSC adsorbent was also characterized by three-step weight losses, however, with a total weight loss of 16.8%. The additional weight loss compared to Fe₃O₄@SiO₂-APTES is attributed to the covalently bonded BTSCs.

Fig. 28. TGA curve of Fe₃O₄, Fe₃O₄@SiO₂-APTES and Fe₃O₄@SiO₂-APTES-BTSC.

2.2.7.7 X-ray Photoelectron Spectroscopy of Fe₃O₄@SiO₂-APTES-BTSC NPs.

The XPS survey spectrum of the Fe₃O₄@SiO₂-APTES-BTSC NP showed signals for Fe, O, Si, N, C, and S at binding energies of 711.39, 532.39, 399.39, 338.72, 284.89, 228.22, and 103.39 eV, respectively (**Fig. 29**).⁹⁸ High-resolution XPS of the C 1s signals shows signals at 284.80, 286.30, 287.80, and 288.80 eV corresponding to different chemical environments such as C-C, C-OH, C=O, O-C=O, respectively.⁹⁹ The small peaks (%Area = 1.38 and 9.31) at 295.32 and 292.00 eV are impurities stemming from CF₃COOH. The N 1s signals of Fe₃O₄@SiO₂-APTES-BTSC at 399.2, 400.6 and 402.8 eV (**Fig. 29**) are related to pyridine N,^{100,101} amide N,¹⁰² and imine N atoms.¹⁰³

Fig. 29. XPS survey spectra of $\text{Fe}_3\text{O}_4@\text{SiO}_2\text{-APTES-BTSC}$.

2.2.8 Synthesis of $\text{SiO}_2\text{-APTES-BTSC}$

N-4-(2-ethylaniline)-thiosemicarbazide was reacted with 4-chloro-isonicotinate-2,6-diacetylpyridine to obtain compound 4-chloro-2,6-diacetyl-pyridine-bis-(4-*N*-2-ethylaniline)-BTSC in 29% yield. The reaction between 4-chloro-2,6-diacetyl-pyridine-bis-(4-*N*-2-ethylaniline)-TSC with APTES pre-functionalized SiO_2 afford $\text{SiO}_2\text{-APTES-BTSC}$. $\text{SiO}_2\text{-APTES-BTSC}$ was subsequently coordinated with Pd^{2+} ions (**Scheme 21**).

Scheme 21. Covalent conjugation of 4-chloro-2,6-diacetyl-pyridine-bis-(4-*N*-2-ethylaniline)-BTSC with $\text{SiO}_2\text{-APTES}$.

2.2.8.1 FT-IR Spectroscopy of SiO₂-APTES-BTSC

4-chloro-2,6-diacetyl-pyridine-bis-(4-*N*-2-ethylaniline)-BTSC shows intense peaks at 748 and 864 cm⁻¹, corresponding to C-Cl and C=S vibration, and the strong band between 1515 – 1588 cm⁻¹ corresponds to C=N stretching based on comparison with 9-undecenal-TSC (**Fig. 30**).⁹⁶ The bands at 2956 and 3330 cm⁻¹ are assigned to asymmetrical stretching of N-H based on comparison with coumarin-thiosemicarbazone and benzaldehyde-TSC.^{104,105} On the bare SiO₂, the intense bands (450 and 1076 cm⁻¹) correspond to the bending and stretching of Si-OH and the asymmetric stretching of the Si-O-Si bond, respectively.¹⁰⁶ On coating SiO₂ with APTES, two additional bands appeared at 1863 and 2982 cm⁻¹ corresponding to C-H and N-H vibration and the deformation of the band at 1634 cm⁻¹ corresponding to Si-O. Additional bands were observed at 1494, 1561 and 2885 cm⁻¹ on covalent functionalization with BTSC; the bands were assigned to N-H bending, C=S vibration, and N-H stretching, compared with ethyl-pyrrole-thiosemicarbazone.⁹³ New bands were observed after the coordination of Pd²⁺ at 668 and 1384 cm⁻¹ assigned to Pd-N and Pd-S stretching.¹⁰⁷

Fig. 30. FT-IR spectra of SiO₂-APTES, SiO₂-APTES-BTSC and SiO₂-APTES-BTSC-Pd Conjugate

2.2.8.2 X-ray Photoelectron Spectroscopy of SiO₂-APTES-BTSC-Pd Nanoparticles

The main peaks observed in the survey scan for SiO₂-APTES-BTSC NPs are Si 2p, Si 2s, Cl 2p, C 1s, N 1s and O 1s centred at 103, 153, 284, 400 and 532 eV (**Fig. 31**). For the survey scan of SiO₂-APTES-BTSC-Pd NPs, additional peaks appeared for Cl 2p and Pd 3d centered at 198 and 338 eV (**Fig. 31**). The absence of Cl 2p in the survey scan of SiO₂-APTES-BTSC is a strong indication that the covalent anchoring of BTSC to SiO₂ NPs was successful.

Fig. 31. XPS survey scan of SiO₂-APTES-H²L and SiO₂-APTES-BTSC-Pd NPs.

The high-resolution XPS analysis of uncoordinated SiO₂-APTES-BTSC for C 1s spectra are deconvoluted into three peaks: C-C (284.5 eV), C-N (286.2 eV), and C=N (288.3 eV) (**Fig. 32**).^{108,109} On coordination with Pd²⁺, C-N (285.9 eV) and C=N (287.9 eV) shifted to a lower binding energies, suggesting that C=N was responsible for binding with Pd²⁺ ions (**Fig. 32**).¹¹⁰ However, the binding energy of C-C (284.6 eV) remains unchanged because C-C was not involved in coordinating Pd²⁺. N 1s spectra are deconvoluted into two peaks: pyridinic N (401.1 eV) and amine (399.6 eV).¹¹¹ On coordination, N 1s spectra are deconvoluted into three peaks, the binding energy of pyridinic N (400 eV) and imine (399.1 eV) shifted to a lower binding energy by 1.1 eV and 0.5 eV. The third peak (401.1 eV) is assigned to Pd-N. S 2p peak was located at 163.5 eV and shifted slightly to a lower binding energy (162.8 eV) by 0.7 eV on coordination with Pd²⁺ (**Fig. 33**).¹¹² Si 2p spectra are deconvoluted into two peaks: SiO₂ (103.1 eV) and Si-O-Si (101.9 eV).¹¹³ SiO₂ shifted slightly to a higher binding energy by 0.2 eV; this may be associated with the interaction of Si atoms with Cl⁻ ions from the K₂PdCl₄ precursor. The Pd 3d spectra are composed of two asymmetric peaks Pd 3d_{3/2} (343.2 and 341.6 eV) and Pd 3d_{5/2} (337.9 and 336.3 eV). These binding energies agree with the expected values of Pd²⁺ (343.2 and 337.9) and Pd⁰ (341.6 and 336.3 eV). Similar binding energies have been reported for Pd²⁺ complexes of dithiocarbamates and [poly(styryl)phenanthroline] complexes.^{114,115} The binding energy for Pd(0) oxidation states is comparable with Pd metals.¹¹⁶⁻¹¹⁸

Fig. 32. XPS high-resolution spectrum of SiO₂-APTES-BTSC NPs.

Fig. 33. High-resolution XPS spectrum of SiO₂-APTES-BTSC-Pd NPs.

2.2.8.3 UV-vis Absorption Spectroscopy of SiO₂-APTES-BTSC Nanoparticles

The UV-Vis absorption spectrum of SiO₂-APTES is characterized by a shoulder at 285 nm (**Fig. 34**).¹¹⁹ 4-chloro-2,6-diacetyl-pyridine-bis-(4-*N*-2-ethylaniline)-BTSC is characterized by an intense absorption band at $\lambda_1 = 344$ nm, corresponding to a $\pi \rightarrow \pi^*$ transition. On covalent anchoring of 4-chloro-2,6-diacetyl-pyridine-bis-(4-*N*-2-ethylaniline)-TSC with SiO₂-APTES, the broad intense absorption band at 344 nm was deformed and shifted to 339 nm (hypsochromic shift).

Fig. 34. UV-vis absorption spectra of SiO₂-APTES NPs, SiO₂-APTES-BTSC NPs and 4-chloro-2,6-diacetyl-pyridine-bis-(4-*N*-2-ethylaniline)-BTSC ligand.

2.2.8.4 Thermogravimetry Analysis of SiO₂-APTES-BTSC

The thermal behaviour of SiO₂, SiO₂-APTES and SiO₂-APTES-BTSC were investigated under N₂ atmosphere over a temperature range between 30 – 800°C (**Fig. 35**). A 10%, 15% and 28% weight loss was observed for SiO₂, SiO₂-APTES and SiO₂-APTES-BTSC NPs, respectively.¹²⁰ The initial weight loss of 10% at temperatures between 30°C and 300°C is attributed to sorbed solvents. The additional 5% and 13% at temperatures between 400°C and 800°C were attributed to the decomposition of APTES and BTSC.

Fig. 35. TGA analysis of SiO₂, SiO₂-APTES and SiO₂-APTES-BTSC

2.2.8.5 Powder XRD Pattern of SiO₂-APTES-BTSC-Pd

All sample patterns appeared amorphous (**Fig. 36**), with a single broad peak,¹²¹ similar to Stöber's results.^{122,123} The non-crystalline nature of the particles is preserved ($2\theta = 21.18$) after functionalizing with APTES and covalently bonding with the TSC ligand.¹²⁴

Fig. 36. PXRD patterns of SiO₂-APTES, SiO₂-APTES-BTSC and SiO₂-APTES-BTSC-Pd NPs.

2.2.8.6 SEM and EDX Investigation of SiO₂-APTES-BTSC-Pd

SEM images showed that the SiO₂-APTES NPs are monodispersed nanospheres with a mean diameter of 207 nm (**Fig. 37**). The diameter of individual particles was calculated using Image J software.¹²⁵ The EDX analysis shows Si and O as the main elemental composition, highlighting the purity of the NPs. On covalent conjugation of SiO₂-APTES NPs with 4-chloro-2,6-diacetyl-pyridine-bis-(4-*N*-2-ethylaniline)-BTSC and coordination with Pd²⁺, the SEM image showed the non-uniform distribution of Pd²⁺ particles on the surface of the SiO₂ NPs (**Fig. 38**).

2.2.9 Synthesis of Fe₂O₃-Dopamine-BTSC

2,6-diacetylpyridine-bis-(4-*N*-chlorophenyl)-TSC was conjugated with Fe₂O₃ (**Scheme 22**) This was achieved by reacting Dopamine pre-functionalized Fe₂O₃ with compound 24 in DMF for 4 days in the presence of Et₃N. The black Fe₂O₃-Dop-BTSC conjugate was recovered via vacuum filtration.

Scheme 22. Conjugation of 2,6-diacetylpyridine-bis-(4-*N*-chlorophenyl)-BTSC ligand with Dopamine pre-functionalized Fe₂O₃ NPs.

2.2.9.1 Powder-XRD Pattern of Fe₂O₃-Dop-BTSC

The PXRD pattern for Fe₂O₃ and Fe₂O₃-Dop-BTSC NP is presented in **Fig 39**. The powder XRD pattern is similar to α -Fe₂O₃¹²⁶. The sharp patterns implied that Fe₂O₃ is more crystalline compared with Fe₂O₃-Dop. On covalent functionalisation with BTSC, Fe₂O₃-Dop-BTSC displayed a significant reduction in the sharp edges, indicating successful covalent functionalisation. The amorphous nature of Fe₂O₃-Dop-BTSC is due to the covalent anchoring of BTSC on the surface of Fe₂O₃.

Fig. 39. Powder XRD pattern of α -Fe₂O₃, Fe₂O₃-Dop and Fe₂O₃-Dop-BTSC NPs

2.2.9.2 FT-IR Spectroscopy of Fe₂O₃-APTES-BTSC

The FT-IR spectra of pristine Fe₂O₃ (**Fig. 40**) are characterized by prominent bands at 452 and 527 cm⁻¹ corresponding to Fe-O bending vibrational modes, while N-H and O-H bending and stretching appeared at 1106 and 3089 cm⁻¹, respectively, due to residual organic content from DMF, PVP and hydrazine. BTSC-Dop is characterized by prominent bands at 1507, 3114 and 817 cm⁻¹ corresponding to N-H, O-H and C=S.¹²⁷⁻¹²⁹ On conjugating dopamine pre-functionalized Fe₂O₃ with BTSC, an additional band was observed for N-H at 2930 cm⁻¹, and other prominent bands were observed at 798, 1081 and 3380 cm⁻¹, corresponding to C=S, N-H bending, and O-H stretching.¹³⁰

Fig. 40. FT-IR spectra of Fe_2O_3 , Fe_2O_3 -Dop and Fe_2O_3 -Dop-BTSC NPs.

2.2.9.3 Thermal Analysis of Fe_2O_3 -Dopamine-BTSC Nanoparticles

The thermogravimetry analysis of the NPs (Fe_2O_3 , Fe_2O_3 -Dop and Fe_2O_3 -Dop-BTSC) between 30 and 800°C (**Fig. 41**), provides an insight into the thermal stability of the NPs. Fe_2O_3 showed two stages of

weight loss: 6.79% between 200 – 250°C and 15.49% between 300 and 550°C, corresponding to the elimination of water molecules and decomposition of organic solvents present in the Fe_2O_3 NPs, respectively.¹³¹ Additional weight loss (17.70%) between 450 and 800°C corresponding to the decomposition of dopamine molecules was observed for Fe_2O_3 -Dop. The final steep weight loss (28.54%) in Fe_2O_3 -Dop-BTSC NPs corresponds to the decomposition of BTSC between 600 – 800°C. This is an indication that the covalent functionalisation was successful. The decomposition of the covalently attached BTSC at a high temperature indicates that Fe_2O_3 -Dop-BTSC NPs have high thermal tolerance.

Fig. 41. TGA analysis of Fe_2O_3 , Fe_2O_3 -Dop, Fe_2O_3 -Dop-BTSC nanoparticles.

2.2.10 Synthesis of Metal Sulfide Nanoparticles

Metal complexes (Cu, Pd, Zn) of 2,6-diacetyl-pyridine-bis-(4-*N*-2-ethylaniline)-BTSC were used for synthesizing metal sulfides NP. The complexes were dissolved in *N*-methyl-2-pyrrolidione solution. Metal sulfide NP was obtained after 10 minutes of decomposition in the microwave (**Scheme 23**). An attempt to synthesize PdSn bimetallic NP was unsuccessful because all the protons in the ^1H NMR spectra could not be assigned. Therefore, the study of the synthesis of bimetallic NP was not explored further.

Scheme 23. Microwave-assisted decomposition of metal complexes of BTSC

2.2.10.1 Thermal Decomposition of Metal Complex of Bis-Thiosemicarbazone

The TGA and DSC thermogram of Cu, Pd and Zn complexes of 2,6-diacetyl-pyridine-bis-(4-*N*-2-ethylaniline)-BTSC were recorded between 30°C and 600°C. The first stage of weight loss, between 30 – 38%, which occurred at 130, 170, and 164°C for Cu, Pd, and Zn complexes, suggests that the complexes do not contain superficial water molecules, and the weight loss is attributed to the degradation of the complexes (**Fig. 42**). This is consistent with the DSC profile. The melting of the complexes commences at 191, 198, and 210°C, respectively. This is followed by the thermal decomposition to form the metal sulfides between 300 and 350°C for all the metal complexes. This is also consistent with the microwave-assisted synthesis of the metal sulfides. Further heating caused the decomposition of the metal sulfides, which corresponded with the final weight loss.

Fig. 42. Thermogravimetry analysis of Cu^{2+} , Pd^{2+} and Zn^{2+} complexes of 2,6-diacetyl-pyridine-bis-(4-*N*-2-ethylaniline)-BTSC. TGA in black and DSC heating (red) and cooling (blue) lines.

2.2.10.2 Powder-XRD Pattern of Metal Sulfide NPs

The diffraction patterns of copper sulfide can be indexed to cubic Cu_7S_4 (digenite, PDF no. 01-072-1966) and the space group $Fm\bar{3}m$. The significant diffraction peaks are at $2\theta = 14.6$ (020), 20.7 (220) and 24.3 (311). Palladium sulfide can be indexed to cubic Pd_{16}S_7 (PDF no. 01-073-9923) and the space group $I\bar{4}3m$. The prominent diffraction peaks are $2\theta = 11.1$ (211), 17.0 (123), 18.2 (040) and 19.3 (411). ZnS can be indexed to the cubic ZnS (sphalerite, PDF no: 01-071-5976) and the space group $F\bar{4}3m$. All the NPs appeared amorphous. No impurity pattern was noticeable in all the synthesized NPs (**Fig. 43**).

Fig. 43. Powder-XRD pattern of $\text{Cu}_{7.2}\text{S}_4$, Pd_{16}S_7 and ZnS NPs.

2.2.10.3 SEM and EDX Investigation of Metal Sulfides NPs

The $\text{Cu}_{7.2}\text{S}_4$ NPs are polydisperse irregular agglomerated particles with rough edges. The average particle size was determined to be 88 nm. The EDX analysis revealed copper and sulfur as prominent peaks with atomic percentages of 24.79 and 11.80%, highlighting the purity of the $\text{Cu}_{7.2}\text{S}_4$ NPs. Pd_{16}S_7 NPs appeared spherical with an average particle size of 78 nm. The prominent peaks are palladium and sulfur, with 58.33 and 32.00% atomic percentages. ZnS appeared to be irregular, with rough edges and polydisperse. The main atoms are Zn (22.02%) and S (17.18%), suggesting that ZnS was obtained pure. C and O atoms are impurities from the device (**Fig. 44 – 46**). The atomic percentage of the metal sulfide NPs is consistent with the PXRD phase.

Fig. 44. SEM image and EDX analysis of $\text{Cu}_{7.2}\text{S}_4$ NP

2.3 Conclusion

This chapter discussed the synthesis of several new pentadentate BTSC ligands by the condensation reaction between thiosemicarbazide and dicarbonyl in acetic acid solution. The condensation reaction

in MeOH did not achieve the desired products, implying the importance of an acidic solution to drive the reaction. The primary focus was to synthesize pentadentate BTSC, which bears an additional functional group, either at the carbonyl backbone or the diamine tails. This was achieved by derivatizing the dicarbonyl backbone or the parent thiosemicarbazide. Complexation of BTSC with Zn^{2+} and Pd^{2+} indicates that the two metal ions bond differently. $[\text{Zn}(\text{BTSC})]$ complex is symmetrical while $[\text{Pd}(\text{BTSC})]$ complex is asymmetry.

The main goal of this thesis is to conjugate BTSC with different NPs covalently. Therefore, a reaction pathway was first established to confirm the condition necessary for the reaction of BTSC with different linkers. Thus, BTSC covalently conjugated dopamine and (3-aminopropyl)-triethoxysilane (APTES). The covalent conjugation of BTSC with APTES in THF achieved the desired products. However, due to solubility concerns, other BTSC derivatives were conjugated with dopamine in DMF. The hydrolysis of APTES was noticeable in DMF, thus causing the loss of at least one ethyl in one arm of the desired product.

EDC/NHS coupling chemistry was initially relied on to conjugate amine pre-functionalized Fe_3O_4 , which was covalently anchored with BTSC. Subsequently, a new condition established in this thesis was relied upon for the covalent anchoring of BTSC with amine pre-functionalized SiO_2 and dopamine pre-functionalized Fe_2O_3 . The chapter concluded with the microwave-assisted decomposition of $[\text{Cu}(\text{BTSC})]$, $[\text{Pd}(\text{BTSC})]$ and $[\text{Zn}(\text{BTSC})]$. The result indicates that high-quality metal sulfides can be synthesized within 10 minutes. An attempt to make bimetallic Pd_2S NP was also successful.

CHAPTER 3. Results and Discussion

3.1 $\text{Fe}_3\text{O}_4@\text{SiO}_2\text{-APTES-BTSC}$ Nanoparticles in Binding Pd^{2+} ions

$\text{Fe}_3\text{O}_4@\text{SiO}_2\text{-APTES-BTSC}$ was used to adsorb Pd^{2+} ions in an aqueous solution. The two UV absorption bands at 210 and 240 nm were used to monitor the absorbance change of Pd^{2+} removal from HCl solutions. The calibration curve is presented in **Fig. 48**. The adsorption of Pd^{2+} with non-functionalized $\text{Fe}_3\text{O}_4@\text{SiO}_2\text{-APTES}$ was also monitored for comparison (**Fig. 48**). The maximum adsorption was achieved after 25 min for $\text{Fe}_3\text{O}_4@\text{SiO}_2\text{-APTES-BTSC}$, while the blank experiment using $\text{Fe}_3\text{O}_4@\text{SiO}_2\text{-APTES}$ showed saturation after 15 min. The time concentration profile, as monitored by UV-vis spectroscopy, showed that the conjugation of $\text{Fe}_3\text{O}_4@\text{SiO}_2\text{-APTES-BTSC}$ with BTSC enhances the affinity for Pd^{2+} .

Fig. 48. UV-vis absorption spectra for the calibration curve used to investigate Pd^{2+} absorbance change (**top**). Time-concentration profile for the adsorption of Pd^{2+} ions using $\text{Fe}_3\text{O}_4@\text{SiO}_2\text{-APTES}$ (**middle**) and $\text{Fe}_3\text{O}_4@\text{SiO}_2\text{-APTES-BTSC}$ (**bottom**) adsorbents.

The adsorption isotherm data were fitted into non-linear Langmuir and Freundlich adsorption equations. The adsorption isotherm data is presented in **Table 6**. The adsorption capacity increased with increasing initial $\text{K}_2\text{Pd}_2\text{Cl}_4$ concentration (**Fig. 49**). The Freundlich isotherm is in keeping with an

adsorption process occurring on a heterogenous surface, it is reversible and non-uniform, while the Langmuir model is best suited for monolayer adsorption.^{132,133} Furthermore, the calculated Freundlich parameters $K_F = 0.4712 \text{ (mg/g)/(mg/L)}$ and $n = 1$ suggest that the adsorption follows a cooperative mechanism, which is in line with multidentate binding of Pd^{2+} in the BTSC pocket. The maximum adsorption capacity for $\text{Fe}_3\text{O}_4@\text{SiO}_2\text{-APTES-BTSC}$ was 793.44 mg/g . For the blank $\text{Fe}_3\text{O}_4@\text{SiO}_2\text{-APTES}$, the adsorption capacity was 270.2 mg/g , an indication that the major adsorption contribution was from the functionalized BTSC unit. Initial solution pH does not have a severe impact on the adsorption capacity. Thus, the $\text{Fe}_3\text{O}_4@\text{SiO}_2\text{-APTES-BTSC}$ can function at a wide pH range. This is attributed to the N[^]S donor atoms of BTSC that can function at opposing pH ranges.²⁰

Table 6. Equilibrium adsorption isotherm data. ^a

Fig. 49. Adsorption isotherm and effect of pH in removing Pd^{2+} ions from an aqueous solution using $\text{Fe}_3\text{O}_4@\text{SiO}_2\text{-APTES-BTSC}$.

3.1.1 $\text{Fe}_3\text{O}_4@\text{SiO}_2\text{-APTES-BTSC}$ Nanoparticles Mechanism in Binding Pd^{2+} ions – (Adsorbed Species).

To gain an insight into the adsorption mechanism, a combination of characterization techniques and modelling was employed. 2,6-diacetylpyridine-bis-(4-*N*-2-pyridyl)-BTSC ([Pd(BTSC)]) was

coordinated with Pd^{2+} . The single-crystal XRD (**Fig. 50**) showed a $\text{S}^{\text{thiolate}}\text{N}^{\text{imine}}\text{N}^{\text{py}}\text{N}^{\text{amide}}$ coordination and the packing clearly showed a Pd–Pd interaction with a distance of 3.323 Å, while the DFT-calculated optimized geometries confirm that this is the most stable species (-60,661.75 eV).

Fig. 50 Molecular structure (**Top**) and packing (**bottom**) of Pd complex of 2,6-diacetylpyridine-bis-(4-*N*-2-pyridyl)-BTSC, projected along the *a*-axis.

However, other calculated configurations, including S^NN^S coordination (60,664.61 eV) and Pd–Cl-containing complex species (-73,206.17 eV), are very close in energy (**Fig. 51**). These species have the S^{thiolate}N^{imine} chelate coordination in common (**Table 7**). Thus, it is assumed that, sooner or later, any initially present thione is deprotonated upon S^{thione}N^{imine} chelate coordination. This thione-thiolate transformation is in agreement with a strong increase in softness^{10,11,69} and is probably driven by the soft but also electrophilic Pd(II).^{10,65,134}

Fig. 51. DFT calculated possible isomers configuration for Pd complex of 2,6-diacetylpyridine-bis-(4-*N*-2-pyridyl)-BTSC.

The geometry of the Cl-containing structure [Pd(BTSC)Cl] with a S^{thiolate}N^{imine}N^{Py}/Cl bonding motive, shows the same preference for pyridine N binding as the experimental and the calculated structure derivative [Pd(BTSC)] but it does not include a six-ring N^N chelate motive. Therefore, it is assumed that the overall chemical preference of Pd(II) to the central pyridine N atom, while the electronically favorable six-ring N^N chelate found in the experimental and calculated structure [Pd(BTSC)] might govern the formation of this structure, but seems not to be a very important feature in binding Pd(II).

Table 6. Selected metrics in experimental and DFT-calculated [Pd(BTSC)] and [Pd(BTSC)Cl] structures.

^c Pd coordinated with two imine.

In agreement with the EDX analysis (**Fig. 52**), the XPS survey scan (**Fig. 53**) showed that Pd–Cl species play a role in final Pd-binding. The adsorption isotherm results are in line with a cooperative adsorption. This agrees with the idea of more than one Pd binding mode contributing to the overall adsorption process. This also agrees with the Pd-BTSC binding models above (**Fig. 50**).

Fig. 52. EDX analysis of $\text{Fe}_3\text{O}_4@\text{SiO}_2\text{-APTES-BTSC-Pd NP}$

The XPS survey spectrum of the $\text{Fe}_3\text{O}_4@\text{SiO}_2\text{-APTES-BTSC-Pd}$ spent-adsorbent showed signals for O, C, N, Cl, Si, S and Pd at binding energies of 532.72, 285.22, 400.22, 199.22, 103.39, 288.22 and 338.72 eV, respectively.⁹³ This is in agreement with the Cl atom found in the EDX analysis (**Fig. 52**). The high-resolution N 1s signals of $\text{Fe}_3\text{O}_4@\text{SiO}_2\text{-APTES-BTSC-Pd}$ at 400.1, 402.1 and 405.1 eV (**Fig. 53**) are related to pyridine N, amide N, and imine N atoms.^{104,135,136} These binding energy values increase significantly by 0.89, 3.16 and 1.53 eV compared to the XPS values N1s of $\text{Fe}_3\text{O}_4@\text{SiO}_2\text{-APTES}$. The Pd 3d peaks centred at 338.40, and 343.71 eV suggests that Pd is predominately Pd^{2+} and was not partially reduced to Pd^0 . Compared with the standard spectra of PdCl_2 (*ca.* 337.9 eV), the binding energy decreased by 0.8 eV.⁹⁸ Together with the finding of Cl, the Pd-binding energy at 343.71 eV suggests a chlorido-Pd(II) complex such as $[\text{Pd}(\text{BTSC})\text{Cl}]$ (**Fig. 51**) as “extracted species”. Similar Pd-binding energies have been reported for $[\text{PdCl}_2(\text{PPh}_3)_3]$ (343.1 eV) and Pd_2F_6 (343.7 eV).^{99,137}

Fig. 53. XPS survey scan and high resolution XPS analysis of $\text{Fe}_3\text{O}_4@\text{SiO}_2\text{-APTES-BTSC-Pd}$ NP

Alternatively, the isotherm adsorption results can also mean that different species are involved in the initial Pd-binding, as shown in **Fig. 54**. This also highlights the potential function of the pending 4-*N*-(2-pyridyl) groups in the $\text{Fe}_3\text{O}_4@\text{SiO}_2\text{-APTES-BTSC}$ adsorbent. Assuming that in an aqueous HCl solution the complex $[\text{PdCl}_4]^{2-}$ is the dominating species, the assumed *initial species A* show $[\text{PdCl}_3]^-$ ion binding to N_{Py} or S_{thione} after cleaving one Cl^- .^{138,139} Very rapidly either an $\text{N}_{\text{Py}}^{\wedge}\text{S}_{\text{thione}}$ (**B**) or $\text{N}_{\text{Py}}^{\wedge}\text{NH}_{\text{amine}}$ (**C**) chelate binding might force another Cl^- cleavage. The initial N_{Py} coordination of the peripheral 4-*N*-(2-pyridyl) group will then be replaced by the typical TSC-type $\text{N}_{\text{imine}}^{\wedge}\text{S}$ bonding, presumably including deprotonation and formation of $\text{S}_{\text{thiolate}}^-$ (**D**). This will lead to another Cl^- cleavage forming the assumed final minor species **E**. The last Cl^- cleavage is forced by another deprotonation and formation of the final (major) product **F**. However, these initial species remain speculative and species such as $[\text{PdCl}_3(\text{H}_2\text{O})]^-$ or $[\text{PdCl}(\text{H}_2\text{O})_3]^+$ resulting from de-chlorination of the $[\text{PdCl}_4]^{2-}$ in the test solutions,^{28,29} might be the first to coordinate to the BTSC ligand.^{138,139}

Fig. 54. Proposed adsorbed Pd-BTSC species.

Table 3.2 compared the adsorption capacity of some reported adsorbents with $\text{Fe}_3\text{O}_4@\text{SiO}_2\text{-APTES-BTSC}$. $\text{Fe}_3\text{O}_4@\text{SiO}_2\text{-APTES-BTSC}$ have outperformed other adsorbents in removing Pd^{2+} from an aqueous solution (Table 7). This is attributed to the BTSC covering the large non-uniform surface area of the $\text{Fe}_3\text{O}_4@\text{SiO}_2\text{-APTES-BTSC}$, as revealed by the SEM image (Fig. 54).

Table 7. Comparison of $\text{Fe}_3\text{O}_4@\text{SiO}_2\text{-APTES-BTSC}$ NPs with other adsorbents used for the removal of Pd(II) ions.

3.2 $\text{SiO}_2\text{-APTES-BTSC}$ Nanoparticles in Suzuki-Miyaura $\text{sp}^2\text{-sp}^2$ Cross-Coupling Reaction

The $\text{SiO}_2\text{-APTES-BTSC-Pd}$ catalyst was investigated for the Suzuki cross-coupling reaction. Bromophenyl and phenylboronic acid were selected for optimization conditions (**Table 8**). The coupling reactions were carried out using different solvents (THF, EtOH and H_2O). EtOH gives the best results (70 %). K_2CO_3 gives the best results among the tested bases (Na_2CO_3 and Et_3N). The catalytic dosage was also varied between 2, 4, and 6 mol%. Increasing the catalytic dosage from 2 to 6 mol% enhanced the formation of biphenyl. However, increasing the reaction temperature from 60 to 100°C did not significantly change the isolated yield. Therefore, the 80°C was selected as the optimal dosage.

Table 8. Optimization of the reaction condition for Suzuki-Miyaura cross-coupling reactions between 1 equivalent bromobenzene and 1.2 equivalent of phenylboronic acid.

9	EtOH	K ₂ CO ₃	0.8	100	81

Reaction conditions: phenylboronic acid (1.2 mmol), bromobenzene (1 mmol), base (6 mmol), 15 mL solvent, 20 hours, inert conditions.

The optimal condition was applied for the synthesis of different bi-aryl compounds. The coupling reaction gave a satisfactory result (**Table 9**). Table 2 shows that substrates with electron-donating groups are isolated in higher yield compared to substrates with electron-withdrawing groups. The highest yield was obtained for diphenyl and 2-methyl-diphenyl. Other authors have reported similar results for TSC complexes used in the Suzuki-Miyaura cross-coupling reactions.^{151,152} The SiO₂-APTES-BTSC-Pd can be recycled up to three times without a significant loss in catalytic activities, highlighting the catalyst stability (**Fig. 3.8**).

3.3 Conclusion

Chapter 3 described the adsorption of Pd²⁺ with Fe₃O₄-APTES-BTSC NP in an aqueous solution. Due to solubility concerns of the Pd source (K₂PdCl₄), Pd²⁺ was accessible in HCl solution. Fe₃O₄-APTES-BTSC exhibits a high adsorption capacity in a wide pH range. The parent BTSC was also coordinated with Pd²⁺ ions. The molecular structure revealed non-symmetric Sthiolate^Nimine^Npyridine^Namide binding modes, and the crystal packing showed Pd-Pd interaction. The fitted isotherm adsorption data showed that the Freundlich isotherm adsorption model best described the adsorption process, which

suggests cooperative adsorption. In lieu, DFT calculation reveals that other binding motifs could be involved in the adsorption process and the EDX and XPS investigations supported this claim.

Chapter 3 concluded by using SiO₂-APTES-BTSC-Pd conjugate as a heterogeneous catalyst in the Suzuki-Miyaura cross-coupling reaction of aryls. SiO₂-APTES-BTSC-Pd conjugate coupled a wide range of aryl in moderate yields and SiO₂-APTES-BTSC-Pd conjugate can be regenerated upto 4 cycle with slight loss in catalytic performance. XPS investigation showed that Pd in SiO₂-APTES-BTSC-Pd catalyst is predominantly Pd⁰, a vital characteristic of the catalyst in the Suzuki-Miyaura cross-coupling reaction.

Chapter 4 Conclusion and Outlook

Bis-thiosemicarbazones (BTSCs) and their metal complexes are known for their biological properties in treatment or imaging. The uncoordinated BTSCs have also been used to probe or sense metal ions in food and beverages. BTSC metal complexes have also found application in homogeneous catalysis. The main drawback to BTSC, which has limited the activities of BTSC as a biological agent, is the challenge of targeting a specific cell. Similarly, unrecovered BTSC employed in sensing metal ions in food and beverages is secondary contamination and potential food and beverage poisoning. Also, additional costs are incurred in homogenous catalysis due to the recovery of spent BTSC catalysts. These shortcomings may be addressed by the covalent anchoring of BTSC onto solid supports (NPs). The large specific surface area characterized by NPs is unique for transporting ligands to target specific cells. Other NPs properties, such as magnetism, would allow for easy recovery of NP–BTSC conjugates.

Therefore, the first objective of the study was achieved by the synthesis of BTSC bearing a carboxylate or chlorido functional group at the diketone backbone or by derivatization of thiosemicarbazide, so that the resulting BTSC bear chlorido functional group at the diamine tail. The functionalized/derivatized BTSC was first reacted with bifunctional linkers, namely, APTES and dopamine, to establish the reaction conditions. The first study involved the synthesis of ester-functionalized BTSC. The hydrolysis of the ester group affords a carboxylate functionalized BTSC. The carboxylate functionalized BTSC was reacted with amine pre-functionalized $\text{Fe}_3\text{O}_4@\text{SiO}_2\text{--APTES}$ via the well-established EDC/NHS coupling chemistry to afford $\text{Fe}_3\text{O}_4@\text{SiO}_2\text{--APTES--BTSC}$ conjugated. The $\text{Fe}_3\text{O}_4@\text{SiO}_2\text{--APTES--BTSC}$ NP was used to adsorb Pd^{2+} ions from an aqueous solution. The $\text{Fe}_3\text{O}_4@\text{SiO}_2\text{--APTES--BTSC}$ NP was characterized by high adsorption capacity (734 mg/g) and can function at a broad pH range (2 – 8). The high adsorption capacity of the $\text{Fe}_3\text{O}_4@\text{SiO}_2\text{--APTES--BTSC}$ NP was attributed to the pentadentate N^S donor atoms, which bind via the S^{thiol}^N^{imine}^N^{pyridinic}^N^{amide} coordination and the cooperative adsorption arises from the combination of minor coordination.

$\text{SiO}_2\text{--APTES--BTSC--Pd}$ was synthesized by reacting amine pre-functionalized $\text{SiO}_2\text{--APTES}$ with Cl-functionalized BTSC in dry THF. $\text{SiO}_2\text{--APTES--BTSC}$ was subsequently coordinated with Pd^{2+} ions. The SEM image of the uncoordinated $\text{SiO}_2\text{--APTES--BTSC}$ NP showed monodispersed NPs, and the EDX analysis and XPS survey scan showed the expected elements (Si, O, N and S). The SEM image of the coordinated $\text{SiO}_2\text{--APTES--BTSC--Pd}$ showed monodispersed NPs with unevenly dispersed Pd^{2+}

particles attached to the surface of the SiO₂-APTES-BTSC NPs. Si, O, N, S, Pd and Cl peaks were identified in SiO₂-APTES-H²L-Pd and the EDX analysis revealed that Pd and Cl were present in ratio 1:1, suggesting that in addition to the S^{thiol}^N^{imine}^N^{pyridinic}^N^{amide} coordination as revealed by single crystal XRD, minor S^{thiol}^N^{imine}^N^{pyridinic}^Cl coordination was also present. High-resolution X-ray photoelectron spectroscopy (XPS) analysis of N 1s, C 1s and S 2p were characterized by a shift to a lower binding energy after coordinating with Pd²⁺, suggesting that these functional groups (C=N, C=S, N-H, pyridinic-N) are responsible for Pd²⁺ coordination. The SiO₂-APTES-H²L-Pd NPs were used in the Suzuki-Miyaura sp² – sp² cross-coupling reaction. The SiO₂-APTES-H²L-Pd catalyst performed reasonably well up to the third catalytic cycle.

The metal complex of thiosemicarbazones has been used as precursors for the synthesis of metal sulfides. The metal sulfide NPs are synthesized via pyrolysis, hydrothermal or thermal decomposition of metal complexes of thiosemicarbazone. These methods require a high amount of energy and a long reaction time. Therefore, an alternate method, such as microwave-assisted decomposition, is preferred due to low energy requirement and short reaction time. Thus, the final study involved the synthesis of copper sulfide, palladium sulfide and zinc sulfide NPs via microwave-assisted decomposition. The BTSC metal complexes (Cu, Pd and Zn) were dissolved in *N*-methyl-2-pyrrolidone and heated for 10 minutes under a microwave. Cu_{7.2}S₄ NPs were obtained in the *Fm*–*3m* space group, Pd₁₆S₇ NPs were obtained in the *I*–*43m* space group, and ZnS NPs were obtained in the *F* –*4 3 m*. All NPs appeared in the cubic phase. The EDX spectra showed the expected peaks, Cu, Pd and Zn, as the metal ion in addition to the S atom, and the atomic percentage agrees with the PXRD phase of the metal sulfide, which alludes to the purity of the NPs. Thus, Cu_{7.2}S₄, Pd₁₆S₇ and ZnS nanocrystals can be synthesized at reduced reaction time and energy.

Future consideration should focus on improving the solubility of the BTSC. The derivatization of the dicarbonyl backbone of the BTSC with halogen, ester, tertbutyl and phenyl did not significantly enhance the solubility. This is evident in the poor solubility of 4-bromo-2,6-diacetylpyridine-bis-(4-*N*-2-pyridyl)-TSC as compared with the unsubstituted 2,6-diacetylpyridine-bis-(4-*N*-2-pyridyl)-TSC. Similarly, the low product yield associated with the diketone backbone is also a significant concern. Thus, an alternate backbone should be considered to improve yield and solubility. The study can also be extended to a method to obtain a uniform distribution of Pd²⁺ in the conjugate by comparing pre and post-functionalization techniques. The release of coordinated metal ions (Pd²⁺) can also be explored to extend the application of NP-BTSC conjugate to biological applications. Finally, future

consideration should be given to the facile synthesis of bimetallic and trimetallic NPs with potential applications in catalysis and as energy storage devices.

Chapter 5 Experimental Section

5.1 Instrumentation.

NMR spectra were recorded on a Bruker Avance II 300 MHz spectrometer, using a triple resonance ^1H , nBB inverse probe head or a Bruker Avance III spectrometer at 499 MHz with a TCI prodigy 5 mm probe head with z-gradient ($^1\text{H}/^{19}\text{F}$, ^{13}C , ^{15}N , ^2H). X-ray structure determination were carried out on a Bruker D8 Venture diffractometer, including a Bruker Photon 100 CMOS detector, Rheinhausen, Germany, at 100(2) K using Mo $K\alpha$ ($\lambda=0.71073 \text{ \AA}$) radiation. The crystal data were collected using APEX4 v2021.10-0.¹⁵³ The structures were solved by dual-space methods using SHELXT, and the refinement was carried out with SHELXL employing the full-matrix least-squares methods on $F_o^2 < 2\sigma(F_o^2)$ as implemented in ShelXle.^{154–156} The non-hydrogen atoms were refined with anisotropic displacement parameters, and hydrogen atoms were included using appropriate riding models.

Cyclic voltammetry was performed at a 100 mV/s scan rate in 0.1 M $n\text{Bu}_4\text{NPF}_6$ solutions using a three-electrode configuration (working electrode: glassy carbon; counter electrode: Pt; reference: Ag/AgCl) and a Metrohm Autolab PG STAT 30 potentiostat with ferrocene/ferrocenium as internal reference.

The Fourier transform infrared (FTIR) spectra were recorded on a PerkinElmer–Spectrum 400 with a Universal ATR sampling accessory in the range 4000 to 400 cm^{-1} . UV–vis absorption spectra were recorded using a Varian 60 Scan spectrophotometer.

Computational studies were performed using ORCA 5.0.2, and def2–TZVP basis sets were used for all atoms.^{157–159} The geometry of all compounds was optimized at the BP86 level of theory, using Grimme's Dispersion correction and the conductor-like polarizable continuum model (CPCM) parametrized for DCM and DMSO as an approximate solvation model.^{160–164} The geometry optimization results were followed up with numerical frequency calculations to confirm the optimized structure's energetic minimum nature, as indicated by the absence of imaginary modes. Chemcraft software was used for visualization of DFT calculation results.¹⁶⁵

Scanning Electron Microscopy (SEM) images were collected using Jeol JSM–65 10 LV QSEM advanced electron microscope with a LaB6 cathode at 20 kV. Dispersive X-ray (EDX) images of the NPs were recorded using REM Zeiss Neon 40 CrossBeam advanced electron microscope with Focused ion beam workstation and STEM detector. The Thermogravimetric analysis (DTA and DSC) of the complexes

were measured on a Perkin Elmer STA 6000, with a temperature range between 30 to 600°C and Scan Rate of 10.0 °C/min under N₂ atmosphere.

XPS measurements were carried out in an ultrahigh vacuum system (base pressure 1×10⁻⁹ mbar). All samples were transferred to the measurement system under nitrogen avoiding air exposure. A nonmonochromatic X-ray source (VG) with Al K α excitation was used, having a photon energy of 1486.61 eV. The emitted photoelectrons were measured using a hemispherical analyzer (Specs Phoibos 100). The XPS data were fitted by Voight profiles using the software "XPSPEAK 4.1".

CuS, PdS and ZnS were synthesised using Anton Paar, Monowave 400 (Microwave Synthesis Reactor). The reactor was set at a temperature of 300°C and a cooling rate of 55°C, stirring at 600 rpm. The reactor's energy was set to 26 W and a pressure of 10 bar. . The powder X-ray diffractograms (PXRD) were recorded on an STOE–STADI MP diffractometer equipped with a Mo–K α 1 radiation (λ = 0.7093 Å) source and operating in transmission mode. Scanning Electron Microscopy (SEM) coupled with Energy

5.2 Synthesis

5.2.1 Synthesis of thiosemicarbazide (Method 1)

N-4-(2-pyridyl)-thiosemicarbazide (**1**)

1.25 g (16.4 mmol) CS₂ at –20 °C was added to a solution of 9.47 g (100.6 mmol) 2-aminopyridine dissolved in 25 mL ice-cold water at 0 °C. Then a solution of KOH (110.58 mmol) dissolved 25 mL H₂O at 10 °C was added to the reaction mixture.

The reaction mixture was stirred for 24 h in a water bath at 10 °C until the colorless solution turned red. The solution was heated at 80 °C for 2 h until all starting materials are consumed. Then 7.0 g (140 mmol) hydrazine monohydrate was slowly added to the hot solution. The solution immediately turned colorless, and heating was continued for 2 h. Colorless needles of 2-pyridyl thiosemicarbazide began to form after cooling. The solid was filtered off, washed with water and diethyl ether, yielding 680 mg (4.04 mmol, 3.8%) colorless needles. Elemental analysis, found (calc. for C₆H₈N₄S, Mw = 168.05 g mol⁻¹), C, 42.91 (42.84), H, 4.18 (4.78), N, 33.73 (33.31), S, 18.68 (19.06). ¹H NMR (300 MHz, DMSO-d₆): δ 12.59 (s, 1H), 10.58 (s, 1H), 8.22 (dd, *J* = 5.3, 1.8 Hz, 1H), 7.76 (ddd, *J* = 8.9, 7.4, 1.9 Hz, 1H), 7.13 (d, *J* = 8.4 Hz, 1H), 7.07–6.97 (m, 1H), 5.23 (d, *J* = 4.3 Hz, 6H), 2.08 (s, 2H).

N-4-(2-ethylaniline)–thiosemicarbazide (**2**) (Method 2)

1.28 g (10.6 mmol) 2-ethylaniline was dissolved in 5 mL deionized water, and the temperature was brought to 0 °C. Thereafter, ice-cold CS₂ (16.4 mmol, 0.99mL) was added to the solution, followed by adding 5 mL cold KOH (11.58 mmol, 0.649 g) solution. The solution was left for 24 h in an ice bath and refluxed for 2 h (80 °C) until 2-ethylaniline was completely consumed. A solution of hydrazine monohydrate (14 mmol, 0.7 mL) was added, and the reaction mixture was heated under reflux for 2.5 hrs. On cooling, a white precipitate was formed. The precipitate was washed with cold water and Et₂O. Single crystals were obtained from a solution of EtOAc and cHex in 1:1 ratio. From the bulk colourless amorphous material. Yield 90%, 1870 mg (195.08 g mol⁻¹, 9.58 mmol) were obtained. Recrystallization from MeOH/DCM led to the isolation of white crystal. ¹H NMR (300 MHz, CDCl₃) δ 9.04 (s, 1H), 8.22 (s, 1H), 7.61 (s, 1H), 7.28 (dd, *J* = 5.9, 2.6 Hz, 3H), 4.03 (s, 2H), 2.67 (q, *J* = 7.6 Hz, 2H), 1.25 (t, *J* = 7.6 Hz, 3H). Elemental analysis for (C₉H₁₃N₃S): found C, 56.01 H, 6.80, N, 21.20 S, 14.24; required C, 55.35 H, 6.71, N, 21.52 S, 16.42. HR-GC-EI/MS: [C₉H₁₃N₃S]⁺, Retention time = 22.90 min, >90%.

N-(3-hydroxyl-2-pyridyl)-thiosemicarbazide (3)

Using method 1. From 2-amino-3-hydroxypyridine, 4.66 g, 50 mmol. Colourless crystalline solid, 2808.1 mg, (184.22 g mol⁻¹, 15.24 mmol, 36%). ¹H NMR (300 MHz, DMSO-d₆): δ 12.43 (s, 1H), 8.33 (s, 1H), 7.72 (d, *J* = 5.1 Hz, 1H), 7.20 (d, *J* = 7.9 Hz, 1H), 6.94 (dd, *J* = 8.0, 5.0 Hz, 1H), 5.24 (s, 2H).

N-4-(3-pyridyl)-thiosemicarbazide (4)

Using method 1. From 3-aminopyridine 4.66g, 50 mmol. Colourless solid, 3124 mg, (184.33 g mol⁻¹, 16.9 mmol, 40%). ¹H NMR (300 MHz, DMSO-d₆) δ 9.28 (s, 1H), 8.69 (d, *J* = 2.6 Hz, 1H), 8.31 – 8.23 (m, 1H), 8.07 (d, *J* = 8.2 Hz, 1H), 7.33 (ddd, *J* = 8.2, 4.7, 0.8 Hz, 1H), 5.24 (s, 2H).

N-(5-methylpyridyl)-thiosemicarbazide (5)

Using method 1. From 5-methyl-2-amino-pyridine, 50 mmol, 5.41g. Colourless solid, 4001 mg, (182.25 g mol⁻¹, 21.9 mmol, 56%). ¹H NMR (300 MHz, DMSO-d₆) δ 12.65 (s, 1H), 10.48 (s, 1H), 8.08 (d, *J* = 5.3 Hz, 1H), 6.94 (s, 1H), 6.86 (dd, *J* = 5.4, 1.5 Hz, 1H), 5.21 (s, 2H), 2.26 (s, 3H).

N-4(2-tert-butylaniline)-thiosemicarbazide (6)

Using method 2. From 5-tert-butylaniline, 50 mmol, 7.46g. Colourless solid, 2459 mg, (223.34 g mol⁻¹, 11.0 mmol, 25%). ¹H NMR (300 MHz, DMSO-d₆) δ 9.64 (s, 1H), 9.07 (s, 1H), 7.69 (s, 1H), 7.50 (d, J = 7.7 Hz, 1H), 7.21 (t, J = 7.9 Hz, 1H), 7.14 – 7.07 (m, 1H), 4.78 (s, 2H), 1.27 (s, 9H).

N-4-(4-aminomethyl-pyridyl)-thiosemicarbazide (7)

Using method 1. From 4-amino-methyl-pyridine, 50 mmol, 5.4g. Colourless solid, 2681 mg, (182.25 g mol⁻¹, 14.7 mmol, 33%) ¹H NMR (300 MHz, DMSO-d₆) δ 8.84 (s, 1H), 8.53 – 8.39 (m, 2H), 7.31 – 7.21 (m, 2H), 4.74 (d, J = 5.8 Hz, 2H), 4.64 – 4.45 (m, 2H).

N-4-(4-chloroaniline)-thiosemicarbazide (8)

Using method 2. From 4-chloroaniline, 42.4 mmol, 5.41 g. White crystalline solid, 3000.7 mg (201.67 g mol⁻¹, 1.49 mmol, 36%). ¹H NMR (300 MHz, DMSO-d₆): δ 9.17 (s, 1H), 7.67 (d, J = 8.3 Hz, 2H), 7.38 – 7.27 (m, 2H), 4.86 (s, 2H).

N-4-(butylamine)-thiosemicarbazide (9)

Using method 2. From butylamine, 50 mmol, 3.66g. Colourless solid, 2960.9 mg (147.24 g mol⁻¹, 20 mmol, 42%) ¹H NMR (300 MHz, CDCl₃) δ 7.78 (d, J = 2.8 Hz, 1H), 7.44 (s, 1H), 3.80 (s, 2H), 3.63 (td, J = 7.2, 5.7 Hz, 2H), 1.69 – 1.53 (m, 2H), 1.48 – 1.32 (m, 2H), 0.96 (t, J = 7.3 Hz, 3H).

5.2.2 Synthesis of Substituted 2,6-diacetylpyridines – General Procedure

Substituted pyridine (40 mmol) was charged into 100 mL H₂SO₄ (0.4 M), then pyruvic acid (2.1 mL, 31.3 mmol), aqueous AgNO₃ (0.15 g, 0.9 mmol in 0.5 mL water) and (NH₄)₂S₂O₈ (11 g, 43.8 mmol) was added. The solution was left to stir overnight at room temperature. The mixture was filtered, and the combined organic fraction was extracted with DCM (150 mL) and dried over anhydrous Na₂SO₄. The crude product was collected via vacuum evaporation and purified using column chromatography (SiO₂, neat DCM).

4-tert-butyl-2,6-diacetylpyridine (10).

From 5.50 g (40 mmol) 4-(*tert*-butyl)pyridine. Column chromatography in CH₂Cl₂, R_f = 0.70. Yield: 1.40 g (6.39 mmol, 17%) colourless amorphous solid. Elemental analysis, found (calc. for C₁₃H₁₇NO₂, M_w = 219.125 g mol⁻¹), C, 70.98 (71.21), H, 7.65 (7.81), N, 6.39 (6.39). ¹H NMR (300 MHz, CD₂Cl₂): δ = 8.20 (s, 2H), 2.75 (s, 6H), 1.36 (s, 9H) ppm.

4-methyl-isonicotinate-2,6-diacetylpyridine (**11**)

From 4-methyl-2,6-diacetylisonicotinate 5.54 g (40 mmol). Column chromatography in CH₂Cl₂, R_f: 0.65. Yield: 1.7 g (7.68 mmol, 21%) colorless amorphous solid. Elemental analysis, found (calc. for C₁₁H₁₁NO₄ M_w = 221.07 g mol⁻¹), C, 59.69 (59.73), H, 4.91 (5.01), N, 6.33 (6.33). ¹H NMR (300 MHz, CDCl₃) δ 8.73 (d, *J* = 1.6 Hz, 0H), 4.01 (d, *J* = 1.5 Hz, 1H), 2.81 (d, *J* = 1.4 Hz, 1H).

4-chloro-2,6-diacetyl-pyridine (**12**)

4-chloropyridine hydrochloric (2.3 g, 1.58 mmol) was dissolved in 5 mL deionized water and basified with saturated NaOH until pH 9. The mixture was extracted with Et₂O (90 mL), the combined organic fractions were dried over anhydrous Na₂SO₄ and the solvent was evaporated in a vacuum to obtain 4-chloropyridine as yellow oil. The freshly obtained 4-chloro-pyridine was discharged into 100 mL H₂SO₄ (0.4 M), then pyruvic acid (2.1 mL, 31.3 mmol), aqueous AgNO₃ (0.15 g, 0.9 mmol in 0.5 mL water) and (NH₄)₂S₂O₈ (11 g, 43.8 mmol) was added. The solution was left to stir overnight at RT. The mixture was filtered and the combined organic fraction was extracted with DCM (150 mL) and dried over anhydrous Na₂SO₄. The crude product was collected via vacuum evaporation and purified using column chromatography (SiO₂, neat DCM). Cl-DAP elute first. ¹H NMR (300 MHz, CDCl₂) δ: 8.16 (s, 2H), 2.75 (s, 6H). Colourless solid, 690 mg (197.62 g mol⁻¹, 3.49 mmol, 22.78 %). Elemental analysis for (C₉H₈NO₂Cl), found: C, 53.44, 4.24, N, 6.44; required C, 54.70, H, 4.08, N, 7.09

4-bromo-2,6-diacetyl-pyridine (**13**)

Using the same method above. From 4-bromo-pyridine hydrochloride. Compound **13** was obtained as a colourless solid. ¹H NMR (300 MHz, CDCl₃) δ 8.33 (s, 1H), 2.75 (s, 4H), 1.55 (s, 1H).

4-iodo-2,6-diacetyl-pyridine (**14**).

From 4-iodo-pyridine using general method. Compound **14** was obtained as a colourless solid. ¹H NMR (300 MHz, CDCl₃) δ 8.55 (d, *J* = 0.6 Hz, 1H), 2.76 (s, 6H).

4-diethyl-phosphonate-2,6-diacetyl-pyridyl (**15**).

4-bromopyridine hydrochloride (6.22g, 32 mmol) was neutralized with saturated NaOH and extracted with diethyl-ether and dried over anhydrous Na₂SO₄, and the solvent was evaporated in a vacuum to obtain 4-bromopyridine as a yellow oil. 4-bromopyridine was reacted with diethyl-phosphite (4.8 mL, 36 mmol) in the presence of triethylamine (5 mL, 36 mmol) using [Pd(P(C₆H₅)₃)₄] (1.88g, 1.62 mmol) under argon. After the coupling reaction, the mixture was extracted with ethyl acetate, and 4-diethyl-phosphonate-pyridyl was obtained by column chromatography using clean ethyl acetate. 4-diethyl-phosphonate-pyridyl was treated with pyruvic acid as described for compound **10**. ¹H NMR (300 MHz, CDCl₃) δ 8.45 (d, J = 13.3 Hz, 0H), 4.12 (dddd, J = 17.2, 10.1, 8.4, 7.1, 3.0 Hz, 1H), 2.72 (s, 1H), 1.28 (td, J = 7.0, 0.6 Hz, 1H).

1,1'-[4-(4-*tert*-butylphenyl)-2,6-diacetyl-pyridine (**16**)

First, 4-(4-(*tert*butyl)phenyl)pyridine was synthesized by Suzuki coupling. Briefly, K₂CO₃ (4 mmol) was dissolved in a degassed solution mixture of EtOH/water (9 mL: 7 mL), followed by the addition of 4-bromopyridine (1 mmol), 4-*tert*-butyl-phenylboronic acid (1.2 mmol) and [Pd(PPh₃)₄] (6 mol%). The resulting mixture was allowed to cool, and the filtrate was collected, extracted three times with EtOAc and dried in a rotary evaporator. The product was purified using column chromatography.

White amorphous solid. (Column chromatography, EtOAc:c-hex, 3:2), (R_f: 0.5) yield, 113 mg (211.14 g mol⁻¹, 0.535 mmol, 53.8%) ¹H NMR (500 MHz, CDCl₃) δ 8.66 – 8.62 (m, 2H), 7.63 – 7.58 (m, 2H), 7.52 (dt, J = 6.6, 2.2 Hz, 4H), 1.37 (s, 9H). On acylation, the desired product was not obtained.

Therefore, 4-bromo-2,6-diacetylpyridine was coupled with 4-*tert*-butylphenylboronic acid using Pd catalyst to obtain 1,1'-[4-(4-*tert*-butylphenyl)-2,6-diacetyl pyridine. White solid (column chromatography, EtOAc:Cyc, 1:1, R_f: 0.4), yield: 190 mg, (295.16 g mol⁻¹, 0.643 mmol, 66%). ¹H NMR: (300 MHz, CDCl₃) δ 8.45 (s, 2H), 7.76 – 7.65 (m, 2H), 7.59 – 7.48 (m, 2H), 2.83 (s, 6H), 1.37 (s, 9H).

5.2.3 Synthesis of pentadentate Bis-Thiosemicarbazone

2,6-diacetylpyridine-bis-(4-*N*-2-pyridyl)-TSC (**17**)

The title compound was synthesized by dissolving compound **1** (6 mmol, 1.0 g) in 100 mL AcOH at 50°C, and 2,6-diacetyl-pyridine (2 mmol, 0.32g) was added. 0.1 mL of AcOH was added to the solution. The mixture was left in a bath sonicator for 4 hours at 50°C. A yellow precipitate was formed, which was washed with cold MeOH and acetone.

After drying, 550 mg (464.14 g mol⁻¹, 1.18 mmol, 59%) of a yellow amorphous material was obtained. ¹H NMR: (500 MHz, DMSO-d₆) δ 15.08 (s, 2H), 11.18 (s, 2H), 8.40 (d, *J* = 5.0 Hz, 2H), 8.21 (d, *J* = 7.8 Hz, 2H), 8.01 (t, *J* = 7.9 Hz, 2H), 7.94 – 7.82 (m, 2H), 7.31 (d, *J* = 8.4 Hz, 2H), 7.15 (t, *J* = 6.3 Hz, 2H), 2.59 (s, 6H). HR-ESI-MS(+) [*m/z*] = 464.14318 ([M + H]⁺, calc. 464.14341), 486.12513 ([M + Na]⁺, calc. 486.12535).

4-methyl-isonicotinate 2,6-diacetylpyridine-bis-(4-*N*-2-pyridyl)-TSC (17-1)

Compound **1** was condensed with compound **11** in 30 mL AcOH solution and 0.5 mL of CF₃COOH. The yellow amorphous solid was washed as described above (EtOAc:Cy, 3:7), (R_f: 0.6), yielding a yellow solid 108 mg (521.14 g mol⁻¹, 0.207 mmol, 65.5%). ¹H NMR (500 MHz, DMSO-d₆) δ 15.09 (s, 2H), 11.20 (s, 2H), 8.58 (s, 2H), 8.38 (d, *J* = 5.0 Hz, 2H), 7.87 (t, *J* = 8.3 Hz, 2H), 7.30 (t, 2H), 7.15 (d, *J* = 6.5 Hz, 2H), 3.97 (s, 3H), 2.60 (s, 6H).

HR-ESI-MS(+) [*m/z*] = 522.14919 ([M + H]⁺, calc. 522.14888), 544.13083 ([M + Na]⁺, calc. 544.13119)

2,6-diacetylpyridine-4-carboxylic acid-bis-(4-*N*-2-pyridyl)-TSC (17-2)

Compound **17-1** was unprotected by hydrolyzing in an alkaline medium: 0.16g compound **17-1** (0.32 mmol) was dissolved in 80 mL DMF. The pH of the solution was then adjusted to 10 using saturated NaOH, until a yellow precipitate (the Na⁺ salt of BTSC) began to form. The reaction was monitored for 3 days through thin-layer chromatography, till the starting material was consumed. The pH of the solution was readjusted to pH = 3 using 4N HCl solution, resulting in the disappearance of the Na⁺ salt. A yellow precipitate was formed. This was stirred for 2 hours and was allowed to stand in the mother liquor for 24 hours in the refrigerator during which it transformed into a brick-red solid. The solid was filtered off and washed with cold water. Yield: 0.056 g (0.11 mmol, 96%) of a brick-red solid. Elemental analysis calc. for C₂₂H₂₁N₉O₂S₂ (M_w = 507.13 g mol⁻¹) (found): C, 52.06 (52.05), H, 4.17 (4.16), N, 24.84 (24.96), S, 12.63 (12.54). ¹H NMR (500 MHz, DMSO-d₆) δ 15.06 (s, 2H), 11.15 (s, 2H), 8.58 (s, 2H), 8.40 (d, *J* = 5.0 Hz, 2H), 7.88 (ddd, *J* = 8.8, 7.3, 1.9 Hz, 2H), 7.32 (d, 2H), 7.15 (t, 2H), 2.61 (s, 6H), (Figure S14 and S15, SI). HR-ESI-MS(+) [*m/z*] = 508.1333 ([BTSC+H]⁺, calc. 508.1333), 530.11526 ([BTSC+Na]⁺, calc. 530.11526).

4-*tert*-butyl-2,6-diacetylpyridine-bis-(4-*N*-2-pyridyl)-TSC (17-3)

The condensation of compound **1** with 4-*tert*-butyl-2,6-diacetylpyridine as described above compound **17-1**. Yellow amorphous material 210 mg (519.20 g mol⁻¹, 0.404 mmol, 44.68%). ¹H NMR (500 MHz, DMSO-d₆) δ 15.03 (s, 2H), 11.16 (s, 2H), 8.41 –

8.37 (m, 2H), 8.28 (s, 2H), 7.87 (ddd, $J = 9.0, 7.4, 1.9$ Hz, 2H), 7.30 (d, $J = 8.3$ Hz, 2H), 7.14 (t, $J = 6.2$ Hz, 2H), 2.58 (s, 6H), 1.37 (s, 9H). HR-ESI-MS(+) [m/z] = 520.20607 ($[M + H]^+$, calc. 520.20601), 542.18776 ($[M + Na]^+$, calc. 542.18795).

4-bromo-butyl-2,6-diacetylpyridine-bis-(4-*N*-2-pyridyl)-TSC (**17-4**)

Reaction of compound **1** with compound **13**. Yellow amorphous material 311 mg (542.48 g mol⁻¹, 1.74 mmol, 67%). ¹H NMR (300 MHz, DMSO-*d*₆) δ 15.11 (s, 2H), 11.23 (s, 2H), 8.35 (d, $J = 33.7$ Hz, 4H), 7.95 – 7.83 (m, 2H), 7.24 (d, $J = 42.3$ Hz, 4H), 2.56 (s, 6H).

4-chloro-butyl-2,6-diacetylpyridine-bis-(4-*N*-2-pyridyl)-TSC (**17-5**)

Reaction of compound **1** with compound **12**. Yellow amorphous material 242 mg (498.02 g mol⁻¹, 2.1 mmol, 51.88%). ¹H NMR (300 MHz, DMSO-*d*₆) δ 15.09 (s, 2H), 11.21 (s, 2H), 8.39 (s, 2H), 8.11 (s, 2H), 7.94 – 7.82 (m, 2H), 7.30 (s, 2H), 7.16 (s, 2H), 2.56 (s, 6H).

4-iodo-butyl-2,6-diacetylpyridine-bis-(4-*N*-2-pyridyl)-TSC (**17-6**)

Reaction of compound **1** with compound **14**. Yellow amorphous material 311 mg (589.48 g mol⁻¹, 1.9 mmol, 67.11%). ¹H NMR (300 MHz, DMSO-*d*₆) δ 15.09 (s, 2H), 11.21 (s, 2H), 8.51 (d, 2H), 8.43 – 8.37 (m, 2H), 7.94 – 7.83 (m, 2H), 7.31 (d, 2H), 7.20 – 7.14 (m, 2H), 2.55 (s, 6H).

4-thiol-2,6-diacetylpyridine-bis-(4-*N*-2-pyridyl)-TSC (**17-7**)

Compound **17-4** (5.24 mmol, 2.43 g) was added to NaHS (6.28 mmol, 0.48 g) in dry DMF solution, the mixture was left to stir for 24 hours at 40°C. The mixture was allowed to cool and dry under vacuum. The yellow solid was washed 4 times with water and washed thrice with cold MeOH. Yield 190 mg. ¹H NMR (300 MHz, DMSO-*d*₆) δ 15.10 (s, 2H), 11.22 (s, 2H), 8.40 (s, 2H), 8.31 – 8.24 (m, 2H), 7.88 (ddd, $J = 9.1, 7.3, 1.9$ Hz, 2H), 7.30 (s, 2H), 7.17 (s, 2H), 2.55 (s, 6H).

1,1'-[4-(4-*tert*-butylphenyl)-2,6-diacetylpyridine-bis-(4-*N*-2-pyridyl)-TSC (**17-8**)

Reaction of compound **1** with compound **16**. Yellow amorphous material 101 mg (595.79 g mol⁻¹, 5.9 mmol, 23.3%). ¹H NMR (300 MHz, DMSO-*d*₆) δ 8.36 (s, 2H), 7.81 (s, 2H), 7.75 (s, 4H), 7.62 (d, $J = 8.0$ Hz, 2H), 2.58 (s, 6H), 1.34 (s, 9H).

2,6-diacetylpyridine-bis-(4-*N*-2-ethylaniline)-thiosemicarbazone (**18**)

Compound **2** (2 mmol, 0.4 g) and 2,6-diacetyl-pyridine (0.67 mmol, 0.11 g) were dissolved in 15 mL AcOH. Then, CF₃COOH (0.1 mL) was added. The mixture was sonicated for three hours at 40 °C. A yellow precipitate was obtained, filtered and washed twice with Et₂O. 150 mg (517.21 g mol⁻¹, 0.284 mmol, 50 %). ¹H NMR (500 MHz, DMSO-*d*₆) δ 10.67 (s, 2H), 10.10 (s, 2H), 8.58 (d, *J* = 7.9 Hz, 2H), 7.79 (q, *J* = 7.7 Hz, 1H), 7.28 (dt, *J* = 11.7, 5.9, 2.4 Hz, 8H), 2.61 (q, *J* = 7.6 Hz, 4H), 2.54 (s, 6H), 1.22 – 1.04 (m, 6H). Elemental analysis for (C₂₇H₃₁N₇S₂): found C, 60.46, 6.24, N, 18.17, S, 10.72; required C, 62.64, H, 6.04, N, 18.94, S, 12.39. HR-ESI-MS(+) [*m/z*] = 518.21551 ([H⁺L+H]⁺, calc. 518.21551), 540.19732 ([H⁺L+Na]⁺, calc. 540.19745).

4-methyl-isonicotinate-2,6-diacetyl-pyridine-bis-(4-*N*-2-ethylaniline)-TSC (**18-1**)

Reaction of compound **2** with compound **11**. Yellow solid, 103 mg (575.21 g mol⁻¹, 0.18 mmol, 60.9 %). ¹H NMR (499 MHz, CDCl₃) δ 9.28 (s, 2H), 8.96 (s, 2H), 8.52 (s, 2H), 7.93 – 7.85 (m, 2H), 7.34 – 7.28 (m, 6H), 3.96 (s, 3H), 2.79 – 2.70 (m, 4H), 2.56 (s, 6H), 1.32 (t, *J* = 7.6 Hz, 6H).

2,6-diacetyl-pyridine-4-carboxylic acid-bis-(4-*N*-2-ethylaniline)-TSC (**18-2**)

In a 50 mL beaker, Compound **18-1** (0.027 g, 0.04 mmol) was dissolved in a mixture of CH₃Cl (2 mL) and MeOH (8 mL), and then NaOH (0.005 g, 0.12 mmol) was added. After 24 hours, the solvent was removed, and the pH of the residual substance was adjusted to 3. The yellow precipitate was filtered and washed with Et₂O, acetone and distilled water (10 mL). Yellow compound. ¹H NMR (499 MHz, DMSO-*d*₆) δ 10.71 (d, *J* = 1.8 Hz, 2H), 10.19 (d, *J* = 3.7 Hz, 2H), 8.75 (s, 2H), 7.36 – 7.15 (m, 6H), 2.64 – 2.59 (m, 4H), 2.55 (s, 6H), 1.18 (t, *J* = 7.6 Hz, 6H). 15 mg (561.20 g mol⁻¹, 0.02 mmol, 57.7 %).

4-*tert*-butyl-2,6-diacetyl-pyridine-bis-(4-*N*-2-ethylaniline)-TSC (**18-3**)

Compound **2** (0.63 mmol, 0.12 g) and compound **10** (0.3 mmol, 0.065g) were dissolved in 50 mL AcOH. Then CH₃COOH (0.1 mL) was added and refluxed for 4 hours at 50 °C. The yellow precipitate obtained was filtered, washed with Et₂O. 91 mg (573.24 g mol⁻¹, 1.59 mmol, 53.5 %). ¹H NMR (499 MHz, CDCl₃) δ 9.24 (s, 2H), 8.92 (s, 2H), 8.01 (s, 2H), 7.92 (dd, *J* = 7.8, 1.9 Hz, 2H), 7.36 – 7.27 (m, 6H), 2.73 (q, *J* = 7.5 Hz, 4H), 2.55 (s, 6H), 1.35 (s, 9H), 1.29 (t, *J* = 7.6 Hz, 6H).

4-chloro-2,6-diacetyl-pyridine-bis-(4-*N*-2-ethylaniline)-TSC (**18-4**)

Compound **2** (1 mmol, 0.195 g) and compound **12** (0.333 mmol, 0.066 g) were dissolved in 10 mL AcOH. Then CF₃COOH (0.1 mL) was added and sonicated for 3 h at 40 °C. Yellow precipitate obtained was filtered and washed with Et₂O. 160 mg (552.16 g mol⁻¹, 0.289 mmol, 29.1 %). ¹H NMR (500 MHz, DMSO-*d*₆) δ 10.67 (s, 2H), 10.20 (s, 2H), 8.72 (s, 2H), 7.37 – 7.21

(m, 8H), 2.61 (q, *J* = 7.6 Hz, 4H), 2.52 (s, 6H), 1.17 (t, *J* = 7.6 Hz, 6H). ¹H NMR (500 MHz, CDCl₃) δ 9.34 – 9.14 (m, 2H), 9.00 (d, *J* = 22.7 Hz, 2H), 7.98 (s, 2H), 7.88 – 7.70 (m, 2H), 7.37 – 7.27 (m, 6H), 2.71 (dd, *J* = 15.0, 7.5 Hz, 4H), 2.52 (s, 6H), 1.29 (dt, *J* = 10.8, 7.6 Hz, 6H). Elemental analysis for (C₂₇H₃₀ClN₇S₂): found; C, 58.74, H, 5.47, N, 17.70, S, 10.61, required; C, 58.73, H, 5.48, N, 17.76, S, 11.61. HR-ESI-MS(+) [*m/z*] = 552.17690 ([H¹L+H]⁺, calc. 552.17653), 574.15889 ([H¹L+Na]⁺, calc. 574.15848).

2,6-diacetylpyridine-bis-(4-*N*-3-hydroxyl-2-pyridyl)-TSC (**19**)

From 2,6-diacetylpyridine (0.2 mmol, 0.03 g) and *N*-(3-hydroxyl-2-pyridyl)-thiosemicarbazide (0.59 mmol, 0.11 g). Yield: Yellow solid, 80 mg, (495.13 g mol⁻¹, 0.16 mmol, 10%). ¹H NMR (300 MHz, DMSO-*d*₆): δ 15.49 (s, 2H), 8.11 (d, *J* = 7.9 Hz, 2H), 7.97 – 7.86 (m, 1H), 7.17 (d, *J* = 4.7 Hz, 2H), 6.73 (dd, *J* = 7.9, 4.7 Hz, 2H), 6.61 (d, *J* = 7.9 Hz, 2H), 2.48 (s, 6H). Elemental analysis (C₂₁H₂₅N₉O₂S₂): Calcd., Exp., C (50.49, 50.49); H (5.04; 5.08); N (25.23, 25.83); S (12.83, 12.98). ESI-MS (*m/z*): [BTSC+H]⁺ Calcd., 500.164, Exp., 500.303.

4-(*tert*-butyl)-2,6-diacetylpyridine-bis-(4-*N*-3-hydroxyl-2-pyridyl)-TSC (**19-3**)

From 4-(4-(*tert*-butyl)-phenyl)-2,6-diacetylpyridine (0.05 mmol, 0.16 g) and *N*-(3-hydroxyl-2-pyridinyl)-thiosemicarbazide (0.14 mmol, 0.03 g). Yield: Yellow solid, 21 mg, (627.79 g mol⁻¹, 0.03 mmol, 21%). ¹H NMR (300 MHz, DMSO-*d*₆): δ 15.44 (s, 2H), 8.30 (s, 2H), 7.75 (d, *J* = 8.0 Hz, 2H), 7.63 (d, *J* = 8.0 Hz, 2H), 6.83 – 6.58 (m, 4H), 2.53 (s, 6H), 1.26 (d, *J* = 24.5 Hz, 9H). (Fig. 5 in the Supplementary Material). Elemental analysis: (C₃₁H₃₇N₉O₂S₂) Calcd., Exp., C (59.31, 59.32); H (5.30; 4.99); N (20.08, 20.13); S (10.21, 10.22). ESI-MS (*m/z*): [BTSC+Na]⁺ Calcd., 650.209, Exp., 659.207.

1,1'-[4-(4-*tert*-butylphenyl)-2,6-diacetyl-pyridine-bis-(4-*N*-3-hydroxyl-2-pyridyl)-TSC (**19-4**)

Reaction of compound 16 with compound 3. Yellow amorphous material 298 mg (627.79 g mol⁻¹, 2.1 mmol, 50.11%). ¹H NMR (300 MHz, DMSO-d₆) δ 15.44 (s, 2H), 8.30 (s, 2H), 7.75 (d, *J* = 8.0 Hz, 2H), 7.63 (d, *J* = 8.0 Hz, 2H), 6.83 – 6.58 (m, 4H), 2.53 (s, 6H), 1.26 (d, *J* = 24.5 Hz, 9H).

2,6-diacetylpyridine-bis-(4-*N*-3-pyridyl)-TSC (20)

Reaction of compound 4 with 2,6-diacetylpyridine. Yellow amorphous material 255 mg (463.58 g mol⁻¹, 1.82 mmol, 40.18%). ¹H NMR (500 MHz, DMSO-d₆) δ 10.55 (s, 4H), 8.70 (s, 2H), 8.59 – 8.54 (m, 2H), 8.40 (s, 2H), 8.14 – 7.95 (m, 2H), 7.86 (t, *J* = 8.1 Hz, 1H), 7.45 – 7.34 (m, 2H), 2.55 (s, 6H).

2,6-diacetylpyridine-bis-(4-*N*-5-methylpyridyl)-TSC (21)

Reaction of compound 5 with 2,6-diacetylpyridine. Yellow amorphous material 399 mg (491.64 g mol⁻¹, 1.23 mmol, 72.6%). ¹H NMR (300 MHz, DMSO-d₆) δ 15.18 (s, 2H), 11.09 (s, 2H), 8.39 (d, *J* = 7.8 Hz, 2H), 8.29 – 8.15 (m, 2H), 8.09 (t, *J* = 7.8 Hz, 1H), 7.98 (d, *J* = 7.5 Hz, 2H), 7.06 (d, *J* = 32.5 Hz, 2H), 2.57 (s, 6H), 2.33 (s, 6H).

4-bromo-2,6-diacetylpyridine-bis-(4-*N*-5-methylpyridyl)-TSC (22-1)

Reaction of compound 5 with compound 13. Yellow amorphous material 210 mg (519.20 g mol⁻¹, 0.404 mmol, 44.68%). ¹H NMR (300 MHz, DMSO-d₆) δ 15.19 (s, 2H), 11.13 (s, 2H), 8.25 (d, *J* = 6.6 Hz, 4H), 7.16 – 6.95 (m, 4H), 6.56 – 6.41 (m, 2H), 2.53 (s, 6H), 2.33 (s, 6H).

2,6-diacetylpyridine-bis-(4-*N*-2-tertbutylaniline)-thiosemicarbazone (22)

Reaction of compound 6 with compound 2,6-diacetylpyridine. Yellow amorphous material 143 mg (573.82 g mol⁻¹, 4.1 mmol, 59.91%). ¹H NMR (300 MHz, CDCl₃) δ 8.26 – 8.17 (m, 2H), 8.05 – 7.91 (m, 1H), 7.87 – 7.79 (m, 2H), 7.38 (q, *J* = 2.1 Hz, 2H), 7.35 – 7.30 (m, 2H), 7.28 – 7.20 (m, 2H), 2.79 (s, 6H), 1.32 (s, 9H).

4-bromo-2,6-diacetylpyridine-bis-(4-*N*-methylpyridyl)-thiosemicarbazone (23-1).

Reaction of 7 with compound 13. Yellow amorphous material 233 mg (570.53 g mol⁻¹, 2.45 mmol, 49.68%). ¹H NMR (300 MHz, DMSO-d₆) δ 10.77 (s, 2H), 9.43 (t, *J* = 6.2 Hz, 2H), 8.66 (d, *J* = 5.9 Hz, 6H), 7.62 – 7.54 (m, 4H), 5.01 (d, *J* = 6.0 Hz, 4H), 2.48 (s, 6H).

2,6-diacetylpyridine-bis-(4-*N*-chlorophenyl)-TSC (24)

From 2,6-diacetylpyridine (0.8 mmol, 0.13 g) and compound **8** (2.4 mmol, 0.48 g). Yield: Yellow solid, 210 mg, (530.49 g mol⁻¹, 0.39 mmol, 16.7%). ¹H NMR (300 MHz, DMSO-d₆): 10.40 (s, 2H), 8.50 (s, 2H), 7.82 (t, *J* = 7.9 Hz, 1H), 7.60 (d, *J* = 8.3 Hz, 2H), 7.40 (d, *J* = 8.3 Hz, 2H), 2.06 (s, 6H). Elemental analysis (C₂₃H₂₅Cl₂N₇S₂): Calcd., Exp., C (52.08, 53.09); H (3.99; 3.99); N (18.48, 18.51); S (12.09, 11.99). ESI-MS (*m/z*): [BTSC+H]⁺ Calcd., 530.074, Exp., 530.074.

2,6-diacetylpyridine-bis-(4-*N*-butyl)-TSC (**25**)

Reaction of compound **9** with 2,6-diacetylpyridine. Yellow amorphous material 201 mg (421.63 g mol⁻¹, 2.1 mmol, 51%). ¹H NMR (500 MHz, DMSO-d₆) δ 10.26 (s, 2H), 8.67 (t, *J* = 6.0 Hz, 2H), 8.39 (d, *J* = 7.9 Hz, 2H), 7.86 (t, *J* = 7.9 Hz, 1H), 3.64 – 3.53 (m, 4H), 2.44 (s, 6H), 1.64 – 1.55 (m, 4H), 1.33 (h, *J* = 7.4 Hz, 4H), 0.92 (t, *J* = 7.4 Hz, 6H).

4-bromo-2,6-diacetylpyridine-bis-(4-*N*-butyl)-TSC (**25-1**)

Reaction of compound **9** with compound **13**. Yellow amorphous material 255 mg (500.52 g mol⁻¹, 1.96 mmol, 44.68%). ¹H NMR (300 MHz, DMSO-d₆) δ 10.26 (s, 1H), 8.84 (t, *J* = 6.0 Hz, 1H), 8.61 (s, 1H), 3.61 (q, *J* = 6.9 Hz, 2H), 2.41 (s, 3H), 1.61 (p, *J* = 7.6 Hz, 2H), 1.33 (q, *J* = 7.5 Hz, 2H), 0.93 (t, *J* = 7.4 Hz, 4H).

4-thiol-2,6-diacetylpyridine-bis-(4-*N*-butyl)-TSC (**25-2**)

Using the method for compound 17-7. Yellow amorphous material 133 mg (453.69 g mol⁻¹, 3.41 mmol, 38.18%). ¹H NMR (500 MHz, DMSO-d₆) δ 10.26 (s, 2H), 8.84 (t, *J* = 6.0 Hz, 2H), 8.61 (s, 2H), 3.66 – 3.58 (m, 4H), 2.41 (s, 6H), 1.65 – 1.55 (m, 4H), 1.33 (h, *J* = 7.6 Hz, 4H), 0.93 (t, *J* = 7.4 Hz, 6H).

4-*tert*-butyl-2,6-diacetylpyridine-bis-(4-*N*-butyl)-TSC (**25-3**)

Reaction of compound **9** with compound **10**. Yellow amorphous material 251 mg (477.73 g mol⁻¹, 1.9 mmol, 47.77%). ¹H NMR (300 MHz, DMSO-d₆) δ 10.31 (s, 2H), 8.48 (t, *J* = 5.8 Hz, 2H), 8.14 (s, 2H), 3.60 (p, *J* = 7.1 Hz, 4H), 3.32 (s, 4H), 2.44 (s, 6H), 1.67 – 1.54 (m, 4H), 1.54 – 1.17 (m, 9H), 0.90 (dt, *J* = 15.9, 7.3 Hz, 6H).

5.2.4 Anchoring Pentadentate Bis-Thiosemicarbazone with Linker

Compound **18-4**–APTES

Compound **18-4** (0.1 g, 0.19 mmol) was dissolved in THF (200 mL), and Et₃N (0.38 mmol, 53 μ L) was added. The mixture was allowed to stand for 2 hours. (3-aminopropyl)triethoxysilane (APTES) (0.37 mmol, 87 μ L) was added to the mixture, stirred for 4 days at room temperature, and dried under vacuum. Yellow powder 100.1 mg (736.34 g mol⁻¹, 73.78 mmol, 62.5 %). ¹H NMR (300 MHz, CDCl₃) δ 9.19 (s, 2H), 8.92 (s, 2H), 7.98 (s, 2H), 7.87 – 7.78 (m, 2H), 7.36 – 7.27 (m, 6H), 5.66 (s, 1H), 3.87 – 3.77 (m, 2H), 3.64 (q, J = 7.3 Hz, 2H), 2.73 (q, J = 7.6 Hz, 4H), 2.52 (s, 6H), 1.58 (s, 9H), 1.48 (t, J = 7.3 Hz, 6H), 1.31 (t, J = 7.6 Hz, 6H), 1.27 – 1.18 (m, 2H). HR-ESI-MS(+) [*m/z*] = 737.344 ([H³L+H⁺]⁺, calc. 737.344).

Compound **19**–Dopamine

Compound **19** (0.04g, 0.075 mmol) was dissolved in 10 mL hot DMF; then, the solution was allowed to cool to room temperature. Et₃N (35 μ L, 0.25 mmol) was added, followed by the addition of dopamine hydrochloride (0.05g, 0.26 mmol). The mixture was allowed to stir for 4 days at room temperature. Cold water was added to the mixture, and the precipitate was obtained by vacuum filtration. Yellow amorphous material 313 mg (763.27 g mol⁻¹, 2.43 mmol, 62.11%). ¹H NMR (500 MHz, DMSO) δ 10.81 (s, 2H), 10.24 (s, 2H), 8.84 – 8.79 (m, 2H), 8.56 (d, J = 7.9 Hz, 2H), 7.86 (t, J = 7.8 Hz, 1H), 7.61 (d, J = 8.0 Hz, 4H), 7.45 (d, J = 8.2 Hz, 4H), 7.39 – 7.32 (m, 2H), 6.69 (s, 2H), 6.56 (s, 2H), 2.79 – 2.59 (m, 4H), 2.55 (s, 6H), 2.44 – 2.30 (m, 4H).

Compound **24**–APTES

Compound **24** (0.1 g, 0.19 mmol) was dissolved in THF (200 mL), and Et₃N (0.38 mmol, 53 μ L) was added. The mixture was allowed to stand for 2 hours. (3-aminopropyl)-triethoxysilane (APTES) (0.37 mmol, 87 μ L) was added to the mixture and stirred for 4 days at room temperature. ¹H NMR (500 MHz, DMSO-d₆) δ 8.52 (s, J = 7.8 Hz, 2H), 7.85 (t, J = 7.9 Hz, 1H), 7.71 – 7.68 (m, 2H), 7.63 (d, J = 8.3 Hz, 4H), 7.43 (dd, J = 8.8, 4.4 Hz, 4H), 6.87 (s, 6H), 3.74 (q, J = 7.0 Hz, 2H), 3.44 (q, J = 7.0 Hz, 6H), 2.53 (s, 6H), 1.48 – 1.38 (m, 2H), 1.35 (s, 8H), 1.14 (t, J = 6.9 Hz, 4H), 1.05 (t, J = 7.0 Hz, 4H), 0.59 – 0.51 (m, 2H).

Compound **19**–CPTES (3-chloropropyltrimethoxysilane)

^1H NMR (300 MHz, DMSO- d_6) δ 8.53 (d, J = 7.9 Hz, 2H), 7.85 (t, J = 7.9 Hz, 1H), 7.75 – 7.57 (m, 4H), 7.50 – 7.37 (m, 4H), 7.29 – 7.09 (m, 2H), 3.74 (qd, J = 7.0, 2.8 Hz, 8H), 3.44 (q, J = 7.0 Hz, 2H), 2.53 (s, 6H), 1.44 (p, J = 7.6 Hz, 2H), 1.21 – 1.09 (m, 6H), 1.05 (t, J = 7.0 Hz, 2H), 0.62 – 0.47 (m, 2H).

5.2.5 Synthesis of metal complexes – general procedure

A stock solution of BTSC (10 mmol) was prepared in hot DMF. 10 mL of the BTSC stock was taken, 5 mmol (70 μL) of Et_3N was added, followed by the addition of 10 mL (10 mmol) of metal salt ($\text{CuCl}_2 \cdot 2\text{H}_2\text{O}$, K_2PdCl_4 or ZnCl_2). After stirring for an hour at room temperature, the solvent was removed, washed with DMF, and dried under a vacuum.

[Cu(BTSC)] for compound **17**. The product was isolated as a dark-blue solid. Yield: 32.00 mg. ($\text{C}_{21}\text{H}_{19}\text{N}_9\text{CuS}_2$, 524.05 g mol^{-1} , 0.06 mmol, 81%). HR-ESI-MS(+) [m/z] = 525.03945 ($[\text{M} + \text{H}]^+$, calc. 525.05736).

[Pd(BTSC)] for compound **17**. The product was isolated as a brick-red solid. Yield: 44.08 mg. ($\text{C}_{21}\text{H}_{19}\text{N}_9\text{PdS}_2$, 567.02 g mol^{-1} , 0.07 mmol, 80 %). ^1H NMR (500 MHz, DMSO) δ 10.30 (s, 1H), 8.87 (d, J = 6.4 Hz, 1H), 8.32 (dt, J = 4.9, 1.4 Hz, 1H), 8.11 (ddd, J = 8.5, 7.2, 1.5 Hz, 1H), 7.99 (d, J = 7.9 Hz, 1H), 7.94 (d, J = 7.8 Hz, 1H), 7.88 (t, J = 7.9 Hz, 1H), 7.67 – 7.59 (m, 2H), 7.38 – 7.28 (m, 2H), 7.09 – 6.96 (m, 1H), 2.52 (s, 3H), 2.40 (s, 3H). HR-ESI-MS(+) [m/z] = 568.03162 ($[\text{M} + \text{H}]^+$, calc. 568.03125).

[Zn(BTSC)] for compound **17**. The product was isolated as a yellow solid. Yield: 40.00 mg. ($\text{C}_{21}\text{H}_{19}\text{N}_9\text{ZnS}_2$, 525.05 g mol^{-1} , 76.00 mg, 0.07 mmol, 77 %). ^1H NMR (500 MHz, DMSO- d_6) δ 15.06 (s, 2H), 11.15 (s, 2H), 8.58 (s, 2H), 8.40 (d, J = 5.0 Hz, 2H), 7.88 (ddd, J = 8.8, 7.3, 1.9 Hz, 2H), 7.32 (d, 2H), 7.15 (t, 2H), 2.61 (s, 6H). HR-ESI-MS(+) [m/z] = 526.05341 ($[\text{M} + \text{H}]^+$, calc. 526.08513), 550.03545 ($[\text{M} + \text{Na}]^+$, calc. 550.06707).

Compound **18** (0.1g, 0.2 mmol) dissolved in THF (10 mL) and Et_3N (0.1 mmol, 14 μL) was added, followed by the addition of the aqueous salts of $\text{CuCl}_2 \cdot 2\text{H}_2\text{O}$, K_2PdCl_4 or $\text{ZnCl}_2 \cdot 2\text{H}_2\text{O}$. After stirring for 60 minutes at room temperature, the solvent was removed, and the crude product was purified by column chromatography.

[Cu(BTSC)] for compound **18**. From 0.03g, 0.2 mmol CuCl₂·2H₂O. The product was isolated as a blue solid. The solid was purified by column chromatography Yield: (silica, DCM: MeOH, v:v = 97:3). 70 mg (578.21 g mol⁻¹, 0.120 mmol, 70 %).

Elemental analysis for (C₂₇H₂₉N₇S₂Cu): found C, 55.56, H, 5.01, N, 15.32, S, 10.27;

required C, 55.99, H, 5.05, N, 16.93, S, 11.07. HR-ESI-MS(+) [*m/z*] = 579.1639 ([H⁺L+H]⁺, calc. 579.2470).

[Pd(BTSC)] for compound **18**. From 0.07g, 0.2 mmol K₂PdCl₄. The product was

isolated as a red solid. Yield: (silica, DCM: MeOH, v:v = 97:3). The precipitate was recovered, washed with cold THF, and air-dried. Brick red solid 81 mg (622.12 g mol⁻¹, 0.072 mmol, 74.58 %). 81 mg (621.10 g mol⁻¹, 0.130 mmol, 65 %).

¹H NMR (500 MHz, DMSO-*d*₆) δ 10.67 (s, 2H), 10.10 (s, 2H), 8.58 (d, *J* = 7.9 Hz, 2H), 7.79 (q, *J* = 7.7 Hz, 1H), 7.28 (dt, *J* = 11.7, 5.9, 2.4 Hz, 8H), 2.61 (q, *J* = 7.6 Hz, 4H), 2.54 (s, 6H), 1.22 – 1.04 (m, 6H).

Elemental analysis for (C₂₇H₂₉N₇S₂): found; C, 53.36, H, 5.30, N, 16.12, S, 10.48, required; C, 52.13, H, 4.70, N, 15.76, S, 10.31. HR-ESI-MS(+) [*m/z*] = 622.1044 ([H⁺L+H]⁺, calc. 622.1043)).

[Zn(BTSC)] for compound **18**. From 0.03g, 0.2 mmol K₂PdCl₄. The product

was isolated as a red solid. Yield: (silica, DCM: MeOH, v:v = 97:3). 78 mg (578.12 g mol⁻¹, 0.134 mmol, 78 %). ¹H NMR (500 MHz, DMSO-*d*₆) δ 1H

NMR: (500 MHz, DMSO) δ 9.82 (s, 2H), 8.38 (t, 1H), 8.14 (d, *J* = 7.9 Hz, 0H), 7.41 – 7.11 (m, 1H), 2.74 – 2.58 (m, 0H), 2.57 (s, 0H), 1.15 (dt, *J* = 19.5, 7.4 Hz, 1H). Elemental analysis for (C₂₇H₂₉N₇S₂Zn): found C, 55.80, H, 5.00, N, 15.88, S, 10.97; required C, 55.81, H, 5.03, N, 16.87, S, 11.03. HR-ESI-MS(+) [*m/z*] = 579.1217 ([H⁺L+H]⁺, calc. 579.1217).

[Zn(BTSC)] from compound **21**

¹H NMR (300 MHz, DMSO-*d*₆) δ 8.98 (s, 2H), 8.17 (d, *J* = 7.9 Hz, 1H), 8.13 (d, *J* = 5.1 Hz, 2H), 8.06 (d, *J* = 1.4 Hz, 2H), 7.87 (d, *J* = 7.8 Hz, 2H), 6.91 – 6.83 (m, 6H), 2.38 (s, 1H), 2.21 (s, 6H).

Zn(BTSC)] from compound **25-1**

¹H NMR (300 MHz, DMSO-*d*₆) δ 10.66 (s, 2H), 9.40 (t, *J* = 6.2 Hz, 2H), 8.67 (s, 2H), 8.52 (d, *J* = 5.0 Hz, 4H), 7.32 (d, *J* = 5.1 Hz, 4H), 4.92 (d, *J* = 6.1 Hz, 4H), 2.47 (s, 6H).

[Pd(BTSC)] from compound **24**

¹H NMR (500 MHz, DMSO-*d*₆) δ 9.56 (s, 2H), 8.35 (t, *J* = 7.8 Hz, 1H), 8.15 (d, *J* = 7.9 Hz, 2H), 7.74 – 7.68 (m, 4H), 7.39 – 7.29 (m, 4H), 2.37 (s, 6H).

[Pd(BTSC)] from compound **25**.

¹H NMR (300 MHz, CDCl₃) δ 8.61 (d, *J* = 56.6 Hz, 0H), 8.11 (t, *J* = 8.4 Hz, 0H), 7.94 (d, *J* = 7.8 Hz, 0H), 7.79 (dt, *J* = 25.1, 7.5 Hz, 0H), 7.63 – 7.49 (m, 0H), 5.06 (d, *J* = 78.8 Hz, 0H), 3.93 – 3.22 (m, 0H), 2.85 – 2.07 (m, 1H), 1.82 – 1.18 (m, 1H), 1.05 – 0.76 (m, 1H).

[Zn(BTSC)] from compound **25**

¹H NMR (300 MHz, CDCl₃) δ 7.80 (t, *J* = 7.8 Hz, 1H), 7.43 (d, *J* = 7.8 Hz, 2H), 3.63 – 3.12 (m, 4H), 2.48 (d, *J* = 5.7 Hz, 6H), 1.58 – 1.44 (m, 4H), 1.35 (q, *J* = 7.3 Hz, 4H), 0.92 (t, *J* = 7.2 Hz, 6H).

5.2.6 Synthesis of Bis-Thiosemicarbazone Nanoparticles Conjugates

Fe₃O₄@SiO₂-APTES-BTSC

In the first part, Fe₃O₄ was prepared via co-precipitation and was subsequently coated with SiO₂ to obtain Fe₃O₄@SiO₂-APTES. In a separate reaction, a thoroughly dispersed Fe₃O₄@SiO₂-APTES (0.2 g, in 15 mL MeOH) was added to a solution of compound **18-2** ligand (0.063 mmol, 0.032 g in 4 mL DMF) and *N,N'*-dicyclohexylcarbodiimide (DCC) (0.08 mmol, 0.016 g) was added as a coupling agent. The reaction was left for 24 hours at 60 °C, and the resulting precipitate (Fe₃O₄@SiO₂-APTES-BTSC) was collected using a magnetic field and was thoroughly washed with MeOH and acetone, dried in an oven at 60 °C.

SiO₂-APTES

Monodispersed SiO₂, and SiO₂-(3-aminopropyl)triethoxysilane = APTES, (SiO₂-APTES), NP were synthesized by dispersing SiO₂ (2g) in dry MeOH (100 mL) and (3-aminopropyl)triethoxysilane (2mL) was added. The mixture was allowed to stir for 24 hours and allowed to age for 24 hours. SiO₂-APTES was collected by vacuum filtration. Elemental analysis for (SiO₂-APTES): C, 12.24, H, 2.86, N, 4.08.

SiO₂-APTES-Compound **18**

To synthesize SiO₂-APTES-BTSC, compound **18-4** (0.2 g) was dissolved in dry THF (20 mL), degassed for two minutes and Et₃N (100 μ L) was added to the solution. SiO₂-APTES (0.5 g) was sonicated in THF (20 mL) solution and added to the mixture. The mixture was allowed to react for four days at room temperature. The mixture was filtered and washed thrice in THF solution. The SiO₂-APTES-H²L NPs were oven-dried at 40 °C for 24 hours. Elemental analysis: C, 4.77, H, 1.37, N, (1.44), S, (0.33).

SiO₂-APTES-Compound **24**-Pd

SiO₂-APTES-BTSC (0.1 g) was dissolved in 50 mL by sonicating for an hour. The sonicated SiO₂-APTES-BTSC was transferred onto a magnetic stirrer, and 5 mL K₂PdCl₄ (1 mmol, 0.32 g) in THF solution was added. The mixture was allowed to stir for an hour. SiO₂-APTES-H²L-Pd was collected by vacuum filtration and washed with 20 mL of water, THF (20 mL) and acetone (20 mL) and dried in an oven (40 °C) for 24 hours.

Fe₂O₃ NPs

Fe₂O₃ nanoparticles were synthesised by dissolving 0.42 g FeSO₄.H₂O and 4.2 g polyvinylpyrrolidone in 120 mL DMF. The solution was heated to 40 °C and 1.6 mL of hydrazine monohydrate was added dropwise. The temperature was raised to 160 °C and maintained for 3 h. Brown precipitates were collected, centrifuged and washed with acetone and distilled water and then dried in an oven.¹²⁷ The dried brown particles were placed in a muffle furnace heated at 500 °C at a heating rate of 10 °C/min for 3 h. Brick-red products were collected.

Fe₂O₃-Dop NPs

Fe₂O₃ (500 mg) was added to 60 mL distilled water. The mixture was sonicated for 40 min, stirred for 24 h⁴⁶, and allowed to age overnight. The Fe₂O₃-Dop samples were collected by centrifuging and washed with distilled water and acetone. Dried dark samples were collected after drying.

Fe₂O₃-Dop-Compound **18** NP

Fe₂O₃-Dop (100 mg) was added to 150 mL DMF. The mixture was sonicated for 30 minutes, and then Et₃N (0.16 mmol, 25 μ L) was added and stirred for 2 h. BTSC (0.16 mmol, 0.084 g) was added and left stirring for 4 days at room temperature. The sample was collected by filtration and washed 4 times, separately with THF, MeOH, distilled water and acetone to remove unreacted BTSC and Et₃N. The sample was oven-dried at 40 °C. [Elemental analysis: C = 12.65, H = 2.44, S = 1.33, N = 1.78].

5.2.7 Applications of Pentadentate Bis-Thiosemicarbazone in Metal Binding and Catalysis

5.2.7.1 Fe₃O₄–APTES–BTSC Nanoparticles for Binding Pd²⁺ Ions

K₂PdCl₄ was used as the Pd(II) source and prepared in a 0.1 M HCl solution to improve solubility. The final pH of the working solution was 4.0. The time-concentration profile study was conducted as follows: 30 mL (3.6 mg/L) of Pd(II) solution was contacted with 0.002 g of the Fe₃O₄@SiO₂–APTES–BTSC adsorbent stirred at 600 rpm. Samples were collected at intervals until 60 mins. The Fe₃O₄@SiO₂–APTES–BTSC was removed using a magnetic field, and the absorbance spectra were recorded. Similar experiment was repeated for the Fe₃O₄@SiO₂–APTES.

The equilibrium isotherm studies were conducted by contacting 5 × 10^{−4} g of the Fe₃O₄@SiO₂–APTES–BTSC with 20 mL of K₂PdCl₄ solution of varying Pd(II) ions initial concentration (mg/L) (i.e., 1, 5, 10, 15 and 20) for 20 hours. The adsorption performance of Fe₃O₄@SiO₂–APTES–BTSC was compared with Fe₃O₄@SiO₂–APTES at 10 mg/L initial concentration. The initial pH of all solutions was 4.3. The effect of pH on the adsorption of Pd(II) was studied by varying solution pH (2.2, 4, 6.1 and 8.2) at 10 mg/L initial concentration. Samples were collected after 20 hours and separated using a magnetic field. Residual Pd(II) ions were analyzed using ICP-MS. The adsorption efficiency (%) and adsorption capacity (q_e) were calculated using Equation 1 and 2, respectively. The obtained equilibrium isotherm data were fitted into the Langmuir (Eq. 3) and the Freundlich (Eq. 4) isotherm Equations. Where C_o and C_e are the initial and final concentration (mg/L), V and m are adsorbate volume (mL) and adsorbent weight (g). K_L (L/mg) and K_F (mg/g)/(mg/L)ⁿ are the Langmuir and Freundlich constant, respectively, and n (dimensionless) is the Freundlich intensity parameter ⁴⁸.

$$\% \text{ Removal} = \frac{C_o - C_e}{C_o} \times 100 \quad (1)$$

$$q_e = \frac{V}{m} \times (C_o - C_e) \quad (2)$$

$$\frac{1}{q_e} = \frac{1}{q_{max}} + \frac{1}{q_{max} \cdot C_e \cdot K_L} \quad (3)$$

$$\log q_e = \frac{1}{n} \log C_e + \log K_F \quad (4)$$

5.2.7.2 SiO₂-APTES-BTSC Nanoparticles in Suzuki-Miyaura Cross-Coupling Reaction

The coupling of phenylboronic acid and bromobenzene was used as the model experiment. In a typical experiment, 15 mL of solvent THF was degassed for 5 minutes, then K₂CO₃ (6 mmol, 0.55 g), bromobenzene (1 mmol, 106 μ L), phenylboronic acid (1.2 mmol, 0.146 g) and SiO₂-APTES-BTSC-Pd (0.2 g) were added. The reaction was refluxed at 80°C for 20 hours. For the optimum catalytic dosage, the amount of SiO₂-APTES-BTSC-Pd was varied (0.4, 0.6, 0.8 g) for 20 hours at 80°C. Relying on the optimum catalytic dosage, the reaction solvents (THF, EtOH and H₂O), temperature (60, 80 and 100 °C) and base (K₂CO₃ or Na₂CO₃ or K₂CO₃) were also varied. The resulting mixture was allowed to cool to room temperature, extracted twice using ethyl acetate (20 mL) and dried over anhydrous Na₂SO₄. The crude product was purified using column chromatography (eluent: DCM/MeOH) to calculate the isolated yield of the individual reactions.

SiO₂-APTES-BTSC-Pd was tested for reuse by recovering the spent catalyst in a centrifuge tube, washed twice with 20 mL of water to remove the base and THF (20 mL) to remove the unreacted substrate and left to dry in the fumehood overnight. The recovered catalyst was used as described above.

5.2.7.3 Microwave Assisted Decomposition of Bis-Thiosemicarbazone Complexes

In a glass tube, 10 mg of BTSC complexes (Cu²⁺, Pd²⁺ and Zn²⁺) of compound **18** was dissolved in 5 mL *N*-methyl-2-pyrrolidone. The lid was tightly closed, and the mixture was placed in a microwave for 10 minutes. The particles formed were filtered and centrifuged thrice in MeOH solution. The particles were air-dried overnight in fumehood. Cu_{7.2}S₄ and Pd₁₆S₇ were black solids, while ZnS was yellow solids.

4-bromo-2,6-diacetyl-pyridine-bis-(4-N-methylpyridyl)-TSC

Compound 24-APTES

Appendix B. X-ray crystallography data

	[Pd(BTSC)]
Empirical formula	C ₂₅ H ₂₇ N ₉ S ₂ Pd
Formula weight (g/mol)	624.07
Crystal system	Triclinic
Space group	<i>P</i> -1
<i>a</i> (Å)	9.5573(15)
<i>b</i> (Å)	11.6598(17)
<i>c</i> (Å)	15.040(2)
α (°)	107.717(5)
β (°)	98.002(5)
γ (°)	97.232(5)
Volume (Å ³) / <i>Z</i>	1555.6(4) / 2
ρ_{calc} (g/cm ⁻³)	1.332
μ (mm ⁻¹)	0.759
Limiting indices	-11 ≤ <i>h</i> ≤ 11
	-14 ≤ <i>k</i> ≤ 14
	-18 ≤ <i>l</i> ≤ 18
Reflection collected	70055
Independent reflections / <i>R</i> _{int}	6353 / 0.1825
Data/restraints/parameters	6353/0/339
goof on <i>F</i> ²	1.793
<i>R</i> ₁ , <i>wR</i> ₂ [<i>I</i> > 2σ(<i>I</i>)]	0.1491
<i>R</i> ₁ , <i>wR</i> ₂ (all data)	0.4403
Residual electrons and holes (e Å ⁻³)	3.36/-1.44

	(BTSC)
Empirical formula	C ₂₉ H ₃₂ N ₇ S ₂
Formula weight (g/mol)	574.73
Crystal system	Orthorhombic
Space group	<i>P</i> 2 ₁ 2 ₁ 2 ₁
<i>a</i> (Å)	6.7174(5)
<i>b</i> (Å)	18.2333(16)
<i>c</i> (Å)	23.8038(19)
α (°)	90
β (°)	90
γ (°)	90
Volume (Å ³) / <i>Z</i>	2915.5(4) / 4
ρ_{calc} (g/cm ⁻³)	1.309
μ (mm ⁻¹)	0.222
Limiting indices	$-8 \leq h \leq 8$
	$-23 \leq k \leq 23$
	$-30 \leq l \leq 28$
Reflection collected	31208
Independent reflections / <i>R</i> _{int}	6201 / 0.0888

Data/restraints/parameters	6201/0/367
goof on F^2	1.025
R_1 , wR_2 [$I > 2\sigma(I)$]	0.1884
R_1 , wR_2 (all data)	0.2246
Residual electrons and holes ($e \text{ \AA}^{-3}$)	0.53/-0.40

	(BTSC)
Empirical formula	$C_{19}H_{31}N_7S_2$
Formula weight (g/mol)	421.63
Crystal system	Monoclinic
Space group	$C2/c$
a (Å)	20.3700(6)
b (Å)	12.6735(4)
c (Å)	9.2550(2)
α (°)	90
β (°)	107.7470(10)
γ (°)	90
Volume (Å ³) / Z	2275.56(11) / 4
ρ_{calc} (g/cm ³)	1.231
μ (mm ⁻¹)	0.253

Limiting indices	$-26 \leq h \leq 26$
	$-16 \leq k \leq 16$
	$-12 \leq l \leq 11$
Reflection collected	27191
Independent reflections / R_{int}	2608 / 0.186
Data/restraints/parameters	2608/0/130
goof on F^2	1.071
R_1 , wR_2 [$I > 2\sigma(I)$]	0.0389
R_1 , wR_2 (all data)	0.0186
Residual electrons and holes ($e \text{ \AA}^{-3}$)	0.43/-0.32

	(BTSC)
Empirical formula	$\text{C}_{25}\text{H}_{32}\text{ClN}_9\text{S}_4$
Formula weight (g/mol)	654.28
Crystal system	Monoclinic
Space group	$P2_1/n$
a (Å)	12.8177(5)
b (Å)	18.3602(6)
c (Å)	14.3460(6)
α (°)	90
β (°)	112.6830(10)
γ (°)	90

Volume (Å ³) / Z	3115.0(2) / 4
ρ_{calc} (g/cm ⁻³)	1.395
μ (mm ⁻¹)	0.431
Limiting indices	-17 ≤ h ≤ 17
	-24 ≤ k ≤ 24
	-19 ≤ l ≤ 19
Reflection collected	27191
Independent reflections / R_{int}	7713 / 0.0207
Data/restraints/parameters	7713/0/376
goof on F^2	1.064
R_1, wR_2 [$I > 2\sigma(I)$]	0.0324
R_1, wR_2 (all data)	0.0824
Residual electrons and holes (e Å ⁻³)	0.46/-0.30

Appendix C. Cyclic Voltammetry

Cyclic voltammograms of Compound **17** (**top**) and its palladium complex [Pd(BTSC)] (**bottom**) measured in 0.1 M *n*-Bu₄NPF₆/THF.

Cyclic voltammograms of Compound **18** (**top**) and its copper, palladium and zinc complex [Pd(BTSC)] (**bottom**) measured in 0.1 M *n*-Bu₄NPF₆/THF. Copper complex was measured in MeCN.

**Erklärung zur Dissertation
gemäß der Promotionsordnung vom 12. März 2020**

„Hiermit versichere ich an Eides statt, dass ich die vorliegende Dissertation selbstständig und ohne die Benutzung anderer als der angegebenen Hilfsmittel und Literatur angefertigt habe. Alle Stellen, die wörtlich oder sinngemäß aus veröffentlichten und nicht veröffentlichten Werken dem Wortlaut oder dem Sinn nach entnommen wurden, sind als solche kenntlich gemacht. Ich versichere an Eides statt, dass diese Dissertation noch keiner anderen Fakultät oder Universität zur Prüfung vorgelegen hat; dass sie - abgesehen von unten angegebenen Teilpublikationen und eingebundenen Artikeln und Manuskripten - noch nicht veröffentlicht worden ist sowie, dass ich eine Veröffentlichung der Dissertation vor Abschluss der Promotion nicht ohne Genehmigung des Promotionsausschusses vornehmen werde. Die Bestimmungen dieser Ordnung sind mir bekannt. Darüber hinaus erkläre ich hiermit, dass ich die Ordnung zur Sicherung guter wissenschaftlicher Praxis und zum Umgang mit wissenschaftlichem Fehlverhalten der Universität zu Köln gelesen und sie bei der Durchführung der Dissertation zugrundeliegenden Arbeiten und der schriftlich verfassten Dissertation beachtet habe und verpflichte mich hiermit, die dort genannten Vorgaben bei allen wissenschaftlichen Tätigkeiten zu beachten und umzusetzen.

Ich versichere, dass die eingereichte elektronische Fassung der eingereichten Druckfassung vollständig entspricht.“

Zugehörigkeiten

- Member of the Gesellschaft Deutscher Chemiker
- Member of the American Ceramic Society
- Member of the Chemical Society of Nigeria

Fachwissen

- Ligand design and synthesis
- Synthesis of coordination complexes
- Ligand Nanoparticles Conjugates
- Air-free Schlenk Line Technique
- DNA extraction and quantification
- Water and wastewater treatment

Fertigkeiten

Instruments: Experience in operating the following instruments and interpretation of the corresponding data:

- Bruker Avance III Spectrometer 300, 400, 499 NMR
- Thermo Scientific LTQ Orbitrap XL Electrospray Ionization Mass Spectra coupled with FTMS Analyzer and (H)ESI Ion-Probe
- Perkin Elmer STA 6000 Thermogravimetric Analysis
- PerkinElmer-Spectrum 400 Fourier transform infrared Spectroscopy
- Varian 50 Scan UV spectrophotometer
- STOE-STADI MP diffractometer Powder X-ray diffractograms

Software: Advanced proficiency in: Microsoft Office, Corel Draw, EndNote X9, MNOVA, SciFinder, Shelxt, Olex, Mercury, Diamond, Chemdraw, ChemDoodle, WinXPow

Konferenzen und Präsentationen

- Ligand Design Workshop, Cologne, Germany – 2023
Paper Presented: Pentadentate Thiosemicarbazones Nanoparticles Conjugates: Synthesis, Characterization and Applications in Binding of metal ions.
- Koordinationschemie-Treffen, Jena, Germany – 2022
Paper Presented: Ligand-Nanoparticle Conjugates of Polydentate Thiosemicarbazones for Heavy Metal Binding
- Kosygin Forum, Moscow, Russia – 2022
Paper Presented: Influence of different Ag/ZnO heterostructures on the removal efficiency of multidrug-resistant *Enterococcus faecium* harboring multiple resistance genes from tap water
- Akure Humboldt Kollege, Nigeria – 2017
Paper Presented: Synthesis and Characterization of solar active nano-calcium ferrite for the reduction of Cr(VI) to Cr(III) in aqua system.
